RIDE IN COMFORT? YES—You can do so on a

BAT MOTOR MANFG. CO., PENGE, LONDON, S.E.20.

WOLF

WOLF MOTORS

Dear Sir, Customs and Excise Office, Chard.

I promised to let you know more about my little 2½ h.p. WOLF-J.A.P. after six months' riding, and now, after that period, I can safely say it comes up to all expectations.

It has run in an absolutely perfect manner, in bad and good weather alike, on very bad roads, and never once let me down.

I can thoroughly recommend it to anyone who desires a reliable and economical lightweight motor cycle.

W. H. WAINWRIGHT.

THE WULFRUNA ENGINEERING CO., LTD., WOLVERHAMPTON.

Matchless

THE PERFECT PASSENGER MOTORCYCLE

IN its capacity as a Delivery Outfit, the Matchless War Model will do more work, will make deliveries more quickly and economically, than many a larger and more expensive delivery vehicle—the sidecar frame of the Matchless will accommodate any form of carrier.

Hundreds of tradesmen are proving daily that the Matchless Delivery Outfit is a profitable war-time investment. May we send you full particulars? We can give delivery from stock.

H. COLLIER & SONS, LTD.,
PLUMSTEAD, S.E.18.

The Central Council of Motoring Organisations.

THERE is no getting beyond the fact that for some time dissatisfaction with the working of existing motoring organisations has become more and more general, and in some quarters this dissatisfaction has received open expression. In a recent issue we made a few remarks on the work of the Auto Cycle Union, and recommended to motor cyclists the advisability of joining this institution at once. Needless to say, we had more in mind than we actually said, and the main point at the back of our minds was the formation of the new United Council, to be formed by committees or deputies from the existing automobile bodies.

The present restrictions all round us and the obviously crying need for some really capable body that will meet the necessities of *all* motorists have prompted many of the moving spirits of the industry to wonder if something could not be done towards preparing a way for better times after the war, and a scheme was suggested by "British Subject" in *The Autocar* of October 13th, which is now on the high road to fruition.

A Central Council is in the course of formation, and is to consist of representatives of all the established motoring bodies. Thus, the Council will automatically operate only in those matters that concern motorists as a whole, and as the commercial users of motors—who, when all is said and done, are by far the most important motorists of the country—are well represented on this body, it will have behind it the fillip of business enterprise as well as that of purely private requirements. The Council is not yet definitely established, as one of the leading organisations is at the present time holding back, and this is typical of the attitude that has characterised many of these bodies in the past. We think, however, that there is very little doubt that ultimately this body will fall into line, and that we shall at last have some organisation that represents every motorist in the country.

Up till now it has been very easy to criticise the inactivity of our various institutions, and it has also been very easy to overlook the cause of that inactivity, which is, that in most instances an agitation on the part of one of these bodies to ameliorate the lot of motorists in general would have been directly opposed to Government measures for the more efficient carrying on of the war. This being the case, most of our organisations have, and we think rightly, done very little or nothing. We do not for one moment suppose or pretend that the new Council will make any immediate difference to the lot of motorists, for obviously the first thing it could do in this direction would be to obtain some concessions on the fuel question, and any such concessions, we are officially informed, would react detrimentally to the Government in its prosecution of the war. We are sure that no intelligent motorist or member of any organisation would wish his motoring prospects to be brightened at the expense of those of the country as a whole.

When the war is over, however, the new Council will find plenty to do, and in our opinion it is important that it should be there to do it. The possibilities of heavy taxation and even, perhaps, the maintenance of some of the present restrictions after the war, are far from being remote fantasies, and we think that no one will deny that one Central Committee or Organisation will be able to put up a much better fight against persecution than will a number of comparatively small independent bodies.

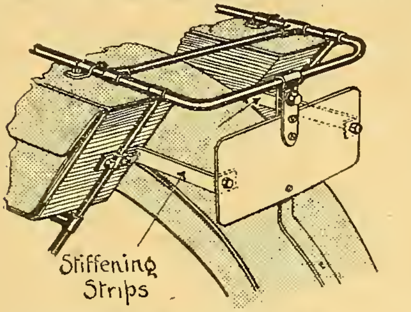
By joining any existing organisation a motorist will be directly helping this United Council in the stupendous task that lies before it; and we cannot do better than to appeal once more to our readers to consider, and we hope, favourably, the question of joining the official motor cyclists' body, the A.C.U.

An index to the advertisements in this issue will be found on the page facing the back cover.

IDEAS: Useful and Ingenious.

STIFFENING REAR NUMBER PLATES.

It is quite a simple performance to provide two stiffeners for the rear number-plate, which will prevent the plate from rattling and breaking off, especially if the rear light is fixed to it. Two pieces of hoop iron and two small bolts are the only articles required.

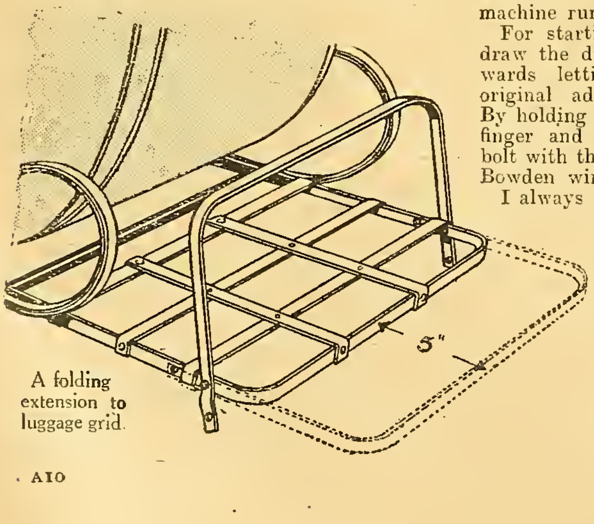


Stiffening strips for number plate to prevent rattle.

First drill holes at the ends of each piece of hoop iron, then bend the ends of each at right angles to each other, and give two coats of black enamel. Holes should then be drilled through the number-plate, and the bolts in the rear end of the toolbags removed, when the stiffeners can be inserted and bolted up, giving firm and stiff supports to the plate.—H. Slater, Doncaster.

EXTENSION TO LUGGAGE GRID.

Owing to the rear springs of sidecar being close to the edge of the grid, the space on the grid in front of springs is not very accommodating for a touring portmanteau. Take off the present grid and drill two holes in each side for ¼in. bolts, procure a piece of ⅜ x ¼in. iron, bend it, and drill for bolts, then obtain four ¼in. bolts with spring washers. Give two coats of black enamel before fixing. When not in use, one bolt from each side can be taken out and the extension folded back out of the way.—H. Slater, Doncaster.

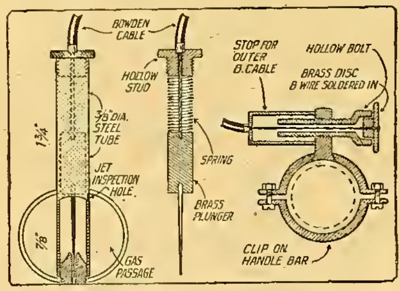


A folding extension to luggage grid.

A VARIABLE JET CARBURETTER.

The sketch I send of the alterations and additions to my Scott carburetter is self-explanatory. Anyone with a few tools can make this device, which has enabled me to obtain 75 to 80 m.p.g. solo and 50-60 m.p.g. with sidecar.

To adjust the jet, set the throttle about one-third open, and air slightly more. Then screw down the needle by turning the cup bolt until the machine misfires. Afterwards gently unscrew until the machine runs at the speed desired.



Fitments for making the standard jet of a Scott carburetter variable.

For starting purposes or hill-climbing, draw the disc back to enlarge jet, afterwards letting go the disc when the original adjustments will be obtained. By holding the disc with the ball of forefinger and thumb and turning the cup bolt with the tips of finger and thumb the Bowden wire is prevented from turning.

I always drive at a fair speed and take advantage of long down grades to save petrol, or substitute, or whatever I have in the tank.

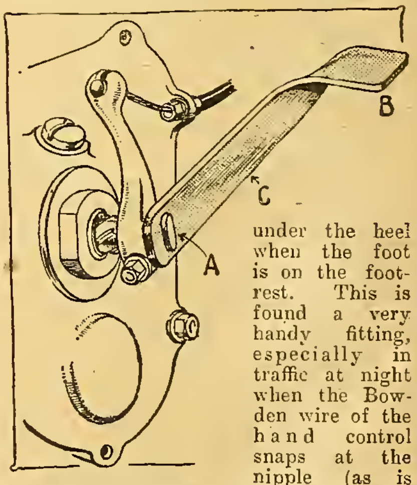
The whole affair was made from the scrap box, except the cup bolt, which is an ordinary Bowden adjusting bolt, and it is well worth the comparatively slight trouble of making.—X 3245, Blythe.

REPAIRING A BURST TUBE

The following wrinkle has been sent to us by a correspondent. In repairing a large burst in a tube it is a good plan to put a patch on *both inside and out.* If the damage to the air tube is a cut or burst large enough to put a finger through it is possible to patch it inside. Take some solution on the finger tip and smear it round the edges of the hole inside; prop the hole open with a piece of card or a splinter of wood, solution a patch, and let both dry. Some little management is necessary to get the patch inside without sticking it in the wrong place, but it can be done by laying the tube across a flat board with the wound uppermost. Get the patch opened out flat against the back of the tube opposite the gash, and press the edges of the hole firmly down upon it. If there is time it is well to leave it for some hours. Then solution a much larger patch on the outside in the ordinary way, only in applying the patch begin at one side and *roll* it over the injured spot.—Ailette.

SIMPLE FOOT CLUTCH CONTROL.

The following simply made foot clutch control for Sturmey-Archer gear has been received from France. A piece of flat thin iron bar, about 10in. long, is first bent at right angles so as to form the piece B. At the other end a hole is drilled and then filed so as to make a driving fit on the end of the worm A. The bar is heated and driven on to the worm, and when cool makes a good tight fit, and the foot control is then fixed. The length of the bar C can be made so as just to rest under the heel when the foot is on the foot-rest. This is found a very handy fitting, especially in traffic at night when the Bowden wire of the hand control snaps at the nipple (as is often the case).—T.M.C. and J.W.M., B.E.F.



A simple foot control for Sturmey-Archer countershaft gear.

OCCASIONAL COMMENTS

BY 'IXION'

Radial Engines for Road Motors.

W. G. ASTON voiced in a recent issue prophecies which have already appeared repeatedly in *The Motor Cycle* and its associated journals, to the effect that the radial engine must ultimately oust the transmogrified motor car engines which at present do duty on the bulk of aeroplanes, and that it further bids fair to rival the vertical types on road motors. How far radial engines, when perfected, will affect the design of motor cycles is a thorny question. They are quite obviously and unquestionably the goods for cycle cars: and if they are more expensive to make than these semi-radials, the V and flat twins, they should nevertheless crop up in increasing numbers on light three and four wheelers soon after the war is over. A three-cylinder radial, with cylinders disposed in the form of a Y, would be just as easily housed as a V in such a machine as the Morgan Runabout, and, while costing little more, would give infinitely better results all round; *a fortiori*, a five-cylinder radial would be better still, but the cost might be prohibitive in a sphere where prices rule keen.

The Radial-engined Motor Bicycle.

STUDYING the same question as it applies to solo mounts, we are up against a second problem besides cost—that of housing the engine. The principle of a radial engine is already accepted, for the V and flat twins are nothing more or less than radials of an inferior and incomplete type. Their existing success proved that cooling a screened cylinder was not impracticable, even before the war, when air-cooling was still in its crude stage: and, as far as this point goes, they show that we can mount a Y or five-cylinder radial longitudinally in the frame. When war broke out, a battle between two types of radial was waging, and was undecided. The V two-cylinder radial was fighting the flat two-cylinder radial, and the battle was drawn for the moment—the flat twin had won on all points bar housing, and this difficulty seemed insuperable except in moderate sizes. The three and five-cylinder radials can easily be housed in tiny sizes. In larger sizes they will be very difficult to accommodate, and will hoist the centre of gravity and the transmission line rather too high. Unless they offer very distinct running advantages over the flat twin, we may see them experimented with for the higher horse-powers only. For example, we may see a five-cylinder, set athwart the frame, tilted backwards a little, and driving by a shaft; or we may see a three-cylinder, set in the plane of the frame, and driving by chain. But the problems are so awkward that the flat twin up to 500 c.c. and the V twin above that limit will quite probably hold their own. One thing is quite evident—the Henderson Co. has shown that under certain production conditions the multiplication of cylinders need not increase the cost of a bicycle, if other reasons render the change desirable.

A Place for the Dynamo Battery.

I AM so completely satisfied with the general merits of a first-class sidecar dynamo outfit, *e.g.*, the Lucas, that I am beginning to yearn for the day when lighting restrictions are ended, and the solo mount *de luxe* can enjoy the blessings of reliable electric light. As I have emphasised *ad nauseam*, the crux of the problem is the battery. There is hardly any freeboard on existing motor bicycles, and it puzzles the wit of man to find room for a sizeable battery. If you fit a small battery trouble sits hard on your trail; the best batteries will not stand eternal charging and discharging at a very high rate, and if you use a powerful head lamp in conjunction with a small battery, it would be exhausted in a very brief spin unless it were simultaneously charged up at a colossal rate. Compare the size and construction of the batteries which Lucas supply for the well under a sidecar seat with the batteries which figured in the few experimental solo sets—hardly any larger than a 5s. 6d. acetylene generator. The spring frame may solve the trouble eventually. No sane man would mount anything as fragile as a battery on a rigid frame carrier, for there road vibration is always doing its durnedest. But the carrier of a first-class spring frame, such as my own A.B.C. possesses, is a haven of peace. We may ultimately shift the toolbags, and dispose a pair of decent batteries one on either side of the carrier in panniers. The tools can go in a bag on the top frame tube, or in a drawer under the carrier grid. Anyhow, we've simply *got* to perfect the solo dynamo outfits somehow; there is no lighting to compare with what they are capable of doing.

A Piston Ring Tip.

IT may be news to some of our readers that an engine can often be cured of plug-sooting propensities by simply turning one or more of the piston rings the other way up. Suppose that a piston ring is only bearing on the cylinder wall with part of its surface. If that surface is along the upper edge of the ring, as shown in fig. 1, every down stroke of the piston wedges oil beneath the underside of the ring, and this oil is squeezed past the bearing surface, and reaches the combustion chamber. If the ring is now inverted (see fig. 2), the bearing part of the surface meets the oil first on the downstroke, and acts as a scraper. Consequently, reversing one or more of the rings may have a considerable influence on the cleanliness of the combustion chamber.

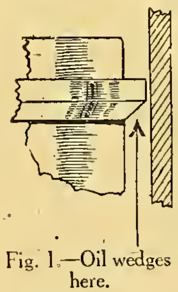


Fig. 1.—Oil wedges here.

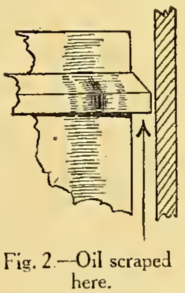

Fig. 2.—Oil scraped here.

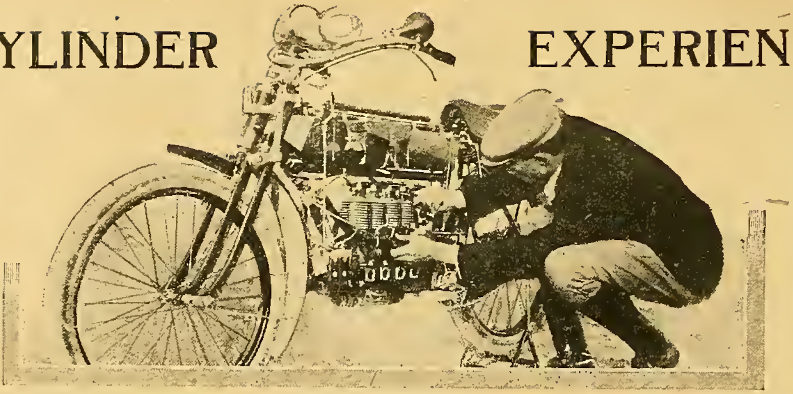
FOUR-CYLINDER EXPERIENCE.



Some Useful Hints and Tips by an Old Rider & Admirer of the Four-cylinder F.N.

As there seems to be a renewal of interest in the four-cylinder engine for motor cycles, the following hints by a former F.N. owner may be found useful. These apply chiefly to the 1910 and 1911 models, but some hold good for other years. By way of preface, it should be remembered by those who fear the extra complication of four cylinders that there are many counterbalancing advantages, such as adequate bearing surface, increased cooling area, smooth and silent running, and the easy application of positive and enclosed transmission by shaft.

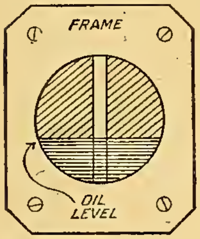


Fig. 1.—Oil level discs.

Starting with the engine. The automatic inlet valves should be inspected at fairly frequent intervals, say 800 to 1,000 miles, and checked for *equal* opening of ⅛in. and equal spring tension, about 12 oz. to open fully, and as the springs are quite cheap it is as well to renew them often. For smooth, powerful running it is most important to guard against air leaks, and to keep the compression good and equal in each cylinder. Although the automatic carburetter functions well a Bowden air inlet is useful, not only for mixture correction, but for running down hill against compression, with the throttle closed, to prevent oil from being drawn past the rings, and also for injecting paraffin after coming in from a run should the inlet valves be inclined to gum up. If one or more cylinders do not fire when starting, the cause is probably a stuck inlet valve, which can be carefully prised open with a screwdriver inserted through the plug orifice. In case of misfiring, to tell which cylinder is missing feel the exhaust pipes.

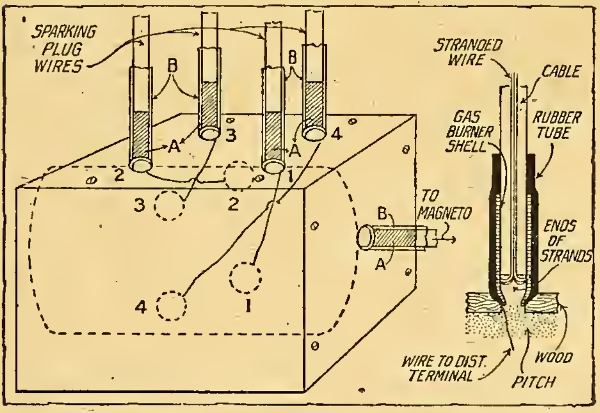

Fig. 2.—The rubber cover for distributer, and section of one of the insulated terminals.

The four oil level windows in the crank case soon get obscured, but this can be overcome by fitting slotted discs of tin behind them (see fig. 1). The level should be about ⅜in. up the glass. As the engine runs at a very high speed the spark plug electrodes need regular attention to keep the gaps equal, and the high-tension distributer should be wiped clean with a rag dipped in petrol. The distributer being in an exposed position the current is liable to short in wet weather, so it is advisable to fit a rubber cover, or, better, a permanent casing, as shown in fig. 2. Misfiring may be caused by one of the exhaust valve tappets touching the lifter bar, thus preventing the valve from seating. If this is so the Bowden wire stop should be slacked off a turn. Continued misfiring will loosen the level casing where it screws in owing to the "chattering" set up, besides causing loss of power and waste of petrol. A slight increase of power may be obtained by drilling four ¼in. holes in the central tube of the silencer—one opposite each exhaust pipe.

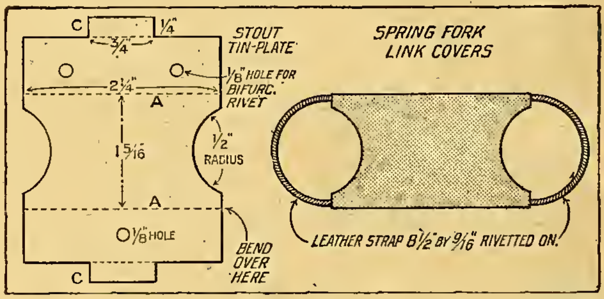

Fig. 3.—Spring fork link covers.

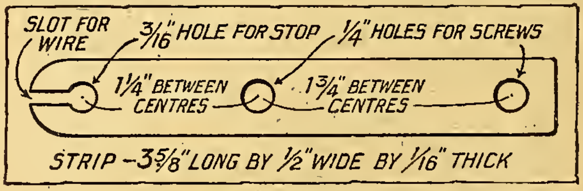

Fig. 4.—An arrangement whereby handle-bar control for the spark can be constructed.

The spring forks are comfortable, but the links soon wear and rattle. This can be obviated by thick leather washers under the upper link retaining bolts and grease packed covers for the lower links made from stout tin and leather strap. See fig. 3.

Four-cylinder Experiences.—

A magneto switch is a useful fitting. The wire from this should run to the screw on the bar which carries the contact breaker cover spring. If desired, handlebar control for the spark advance can be arranged by fitting a plate for the Bowden wire stop under the oil tank. See fig. 4 for measurements.

If pedalling gear is fitted this may as well be replaced by footboards fixed to the rests at the forward ends and supported at the rear by angle irons from a rod through the bracket shell, as shown in fig. 5.

In conclusion, the F.N. is a machine which well repays one for attention, and given this it will be found both fast and reliable, beating any single or twin for staying power. A trial run will convince anyone that the four-cylinder is the engine of the future on account of its power, smoothness, absence of vibration, remarkable acceleration, and ease of starting, to say nothing of the weather-proof transmission.

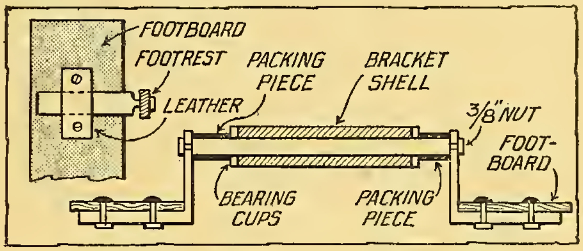

Fig. 5.—Section of footboards, which are fitted in place of pedals.

The National Motor Cyclists' Fuel Union.

The Body created to obtain Fuel Supplies for Motor Cyclist Munitioners.

SOME mention has already been made in these pages of the above institution, and a few facts concerning its work cannot fail to interest our readers. The Union was founded by a few of the principal men in the Engineering Department of an important Midland manufacturing firm, and its object is national in scope and patriotic in character, as it intends to provide for the indispensable fuel requirements of those motor cyclists who need their machines in connection with their work, work which is of national importance.

There are probably over 20,000 motor cyclists in this country who come under this category, most of these being engaged in the engineering and shipbuilding industries.

Not a Joy-riders' Union.

The Union has no sympathy with, and will not in any way encourage, "joy-riding," though it does urge that in certain special cases a just claim can be made for a reasonable amount of recreative motor cycling.

The men in whose interests the Union has been formed work long hours—often thirteen hours a day for seven days a week, with a very large measure of night work—and as their work is of a difficult and arduous character, it is essential that their health should be well looked after. It is quite clear that if we are to get the best out of these men, who are working so strenuously to win the war, they ought to be looked after to the best of the nation's ability. They do not ask for much, but they do ask that they may be supplied with petrol or petrol substitute to the extent of two gallons a month, so as to enable them to get to and from their works quickly, and also in many cases to give them the only opportunity they have of seeing their families at least once a month. Numbers of these men live a considerable distance from the factories in which they are engaged; train journeys are slow, expensive, and not always convenient, while if they were allowed to travel by road they would often be able to make more time in the factory, and also get the benefit of a run in the fresh air instead of a ride in the crowded, germ-laden atmosphere of a railway train.

It is pointed out that if the whole of the motor cyclists in the kingdom were entitled to make a claim of the character indicated and were provided with, say, two gallons of petrol per month, the total consumption for one year would only be equal to about one-eighth of a cargo of petrol.

It is intended that no claim should be encouraged unless the case be a deserving one. It is, therefore, suggested that the applicant should get his requisition countersigned by his employer, and, further, that the Auto Cycle Union, as an independent body, should scrutinise every such application before submitting it to the Government Department concerned. It has also been suggested that the worker whose claim is admitted should carry a signed badge on some conspicuous part of the machine, showing its registered number and the name of the works at which he is employed, so that the information is available to the police at any time.

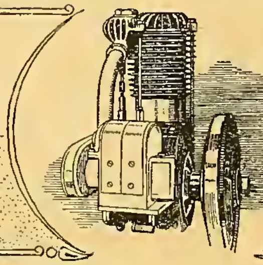
There is another aspect of the matter of which the War Office may not lose sight. Lord French has on more than one occasion reminded us of the possibilities of invasion. It would be of the very greatest value to the military authorities if they could rely on a body of motor cyclists in every munitions area who would be instantly ready with their machines in order to assist the troops. It is believed that the members of the Union would readily link up with the volunteer forces of the country if this became desirable, and would gladly accept this as a condition of their obtaining a supply of fuel.

Where to Apply.

All motor cyclists engaged in national work in need of the assistance indicated should write for particulars of this Union to the Secretary of the Auto Cycle Union, 83, Pall Mall, London, S.W.1, who will immediately put them into communication with the local secretary for that area, and assist in every way possible with regard to their claim.

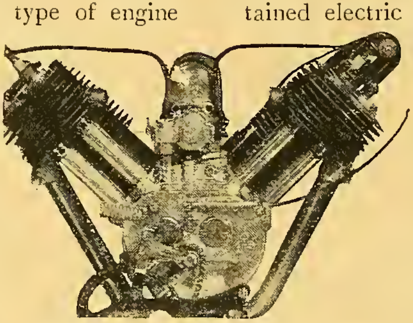
Major T. W. Loughborough, secretary of the Auto Cycle Union, is at present acting as secretary of the London Committee of the Union, while Mr. A. W. Torkington, a member of the Auto Cycle Union Committee, is the chairman. The aims of the Union appear to be perfectly sound and patriotic, and therefore it deserves the support of all motor cyclists who are engaged in national work.

Which Type of Multi-cylinder Engine?



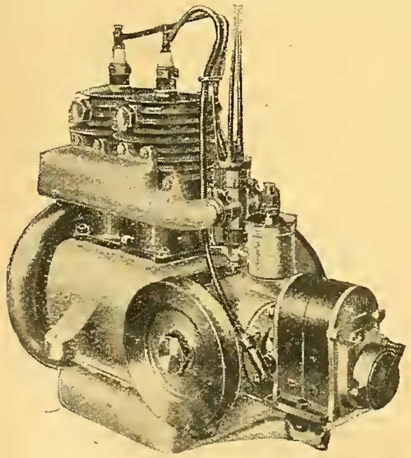
POST-WAR DEMANDS, AND A FEW NOTES ON VARIOUS ENGINE DESIGNS.

THREE types of machines that will find a ready market after the war are: (1.) A flat twin solo mount of, say, 3½ h.p., with overhead valves, outside flywheel, and hot stuff engine; three-speed gear with a wide diameter clutch, capable of withstanding indefinite slipping (with this type of engine one uses the clutch more than with any other type), and all chain drive, partially enclosed—a machine purely for solo work, weighing no more than a Douglas, capable of a speed burst of 58 m.p.h. and of easily holding 42 m.p.h. One of the chief aims in the designing of this mount should be the general reduction in weight. A magneto-dynamo in the flywheel might be utilised, and a much lighter gear box than those at present in vogue could be fitted. Mr. Harry Reed recently showed the writer a two-speed box no larger than a doughnut, which he used some years ago on a powerful racing tricycle having a solid drive. The whole thing weighed only a few ounces, and it proved conclusively that present-day gear boxes are unnecessarily spacious and weighty.



The 90° twin P. and M. engine—a beautifully finished unit of attractive layout. Note the magneto drive.

(2.) The type of machine that I would set down as marking a second ideal is a 5 h.p. three or four-cylinder dual purpose mount of approximately the same weight as the R.F.C., P. and M., having side by side valves, a well silenced engine, and four-speed gear. Outside its suitability for sidecar work, this machine would meet the demands of that vast number of riders who are neither speed merchants nor potterers, who like to ride a comfortable and controllable solo mount possessing ample power, and who take a modest delight in occasional speed dust-ups with other riders.



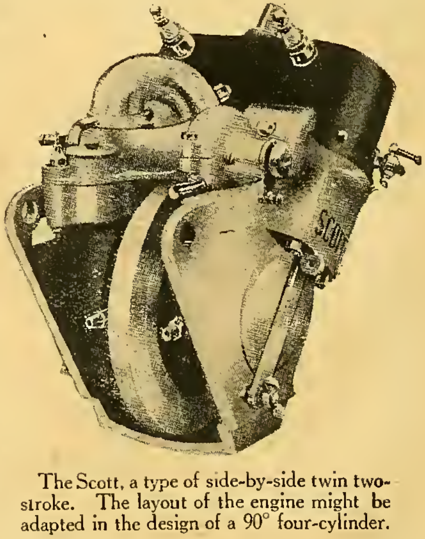
The Premier two-stroke vertical twin. The compact arrangement of the whole unit is at once noticeable.

(3.) Here again I would go all out for the vertical four-cylinder engine, and experience seems to indicate that 8 h.p. is the very lowest for all sidecar work and that 10 h.p. is preferable. A 6 h.p. engine needs to be kept in respectable tune if it is to take a luxurious family sidecar in all weathers, and in the model now advocated manufacturers might spread themselves out in the production of a *modèle de luxe*. Self-contained electric lighting, of course, shaft drive, three or four-speed gear box, and something really attractive in the way of finish. I would vote for the integral unit system, with a minimum of oil leaking joints, the flywheel clutch to be metal-to-metal, and, with the gear box fed with the overflow oil from the engine. Weight would not be a matter of much consequence, and 700 × 80 mm. tyres should be fitted. These are really a great comfort, and it is surprising how they enable one to drive fast over pot-holes without the least discomfort.

As regards the problem of spring frames, I am purposely leaving these out of the question. On our British highways and byways, if one is given a good saddle, a spring seat-pillar and large diameter wheels, one is happier than if in the possession of an inferior spring frame, but it is, of course, to be hoped that the really efficient article will result from the efforts now being made.

Balance and Torque.

While on the subject of ideal mounts it will be interesting to discuss the various types of multi-cylinder engines applicable to motor cycles. In deciding upon the disposition of the cylinders we are up against three ruling factors—balance, torque, and the question of housing the engine in a well designed frame. Balance is the most important of the three. By employing a perfectly balanced and consequently vibrationless engine, not only do we add greatly to the comfort of riding, but we are enabled to



The Scott, a type of side-by-side twin two-stroke. The layout of the engine might be adapted in the design of a 90° four-cylinder.

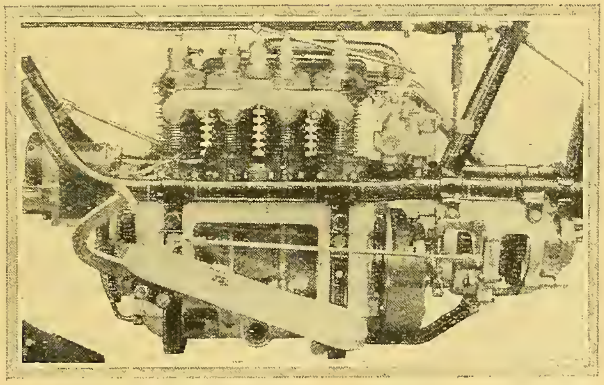
Which Type of Multi-cylinder Engine ?—

employ lighter frames and lighter parts throughout. It is on account of the perfect balance of the flat twin (taking it that the couple is practically eliminated) and the good balance of the four-cylinder, that the futures of these two types are assured, but there are one or two other types almost equally attractive.

As regards torque, I have come to the conclusion that with present-day high revving engines, anything within the limits of reason will do. Certainly it is not worth while to sacrifice the minutest degree of balance to obtain improved torque. Given a well balanced engine and a good silencer one is unable to tell at speeds over 15 m.p.h. whether the torque is good or indifferent. The 90° twin is inferior in torque to the 45°, yet there is no comparison between the two as regards sweet running. The 90° is an engine to be wholeheartedly encouraged in spite of its mediocre torque, while the 45° does not possess one single recommending feature, except that it enables one to cram two cylinders into the conventional type of frame without troubling and worrying to think out something better.

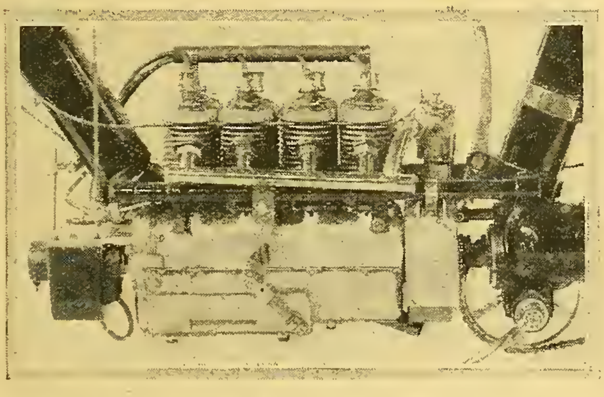
Housing the Engine.

The question of housing the engine is another point that may be lightly dismissed. It may delay for a time the general popularity of a certain type, but, if that type is good, it is bound to come in the end—as witness the flat twin! A few years ago the difficulty of housing the flat twin seemed almost insurmountable, but I have recently seen several new frame designs that leave nothing to be desired.

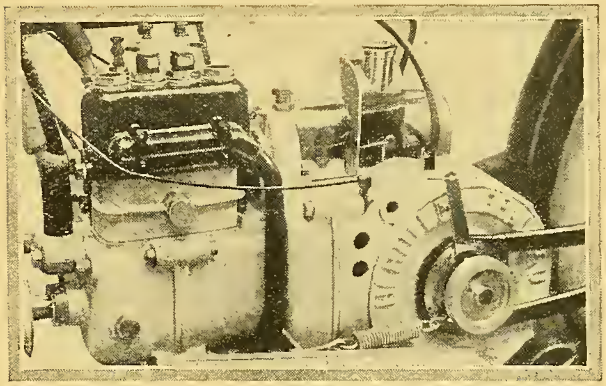


The four-cylinder F.N. unit, exhibition finish, the crank case being cut away to show the cranks *in situ*, similarly the flywheel to show the clutch—one of the neatest and most attractive motor cycle units ever produced.

The three-cylinder vertical is another type of engine which deserves more attention than it has received hitherto. Its balance is as good as, and in some respects better than, the four, though its torque is, of course, slightly inferior. The argument that it never met with success in car practice does not signify anything. In car design space under the bonnet is of little consequence, and if one could employ three cylinders one might as well go the whole way and employ four. Therefore there was nothing particularly to recommend the three-cylinder, whereas, in motor cycle practice, the length of the engine is all important, and the reduction of an inch or two here may remove a whole host of frame design difficulties otherwise to be met. The one objection to the four-cylinder, indeed, is the inevitably increased length of wheelbase it demands—brought about not only by the length of the engine but by the fact that the flywheel and gear box must be placed directly behind it, more or less amidship of the frame.



The Pierce, an American four-cylinder production, which presented numerous original features. Oil and petrol were carried in the hollow frame. Note the shaft drive and gear box housing. The whole layout of the unit is extremely neat and compact.



A 3 h.p. monobloc vertical water-cooled twin, a French production —Motocyclette Herdtlé-Bruneau of about 1913.

An Unconventional Design and Two-stroke Engines.

The 90° four-cylinder is another highly possible proposition, having its cranks and flywheel arranged similarly to those of the Scott, but with double big ends and cranks set at 90°. This engine would be easy to house and very accessible, while its torque would be excellent and its balance perfect. It would be vastly interesting to see what could be done in this line.

The side by side two-cylinder is off the boards for more than one reason. One must have either abominable torque or no balance at all. If the pistons move in unison, then one can obtain even firing intervals, but the balance is no better than in a single; if the piston strokes are opposed, then the balance is good, save for a considerable couple, but the torque is worse even than a 90° twin.

The latter remarks apply, of course, to four-stroke engines only. With the Scott two-stroke the power impulses are even, and, the piston strokes being

Which Type of Multi-cylinder Engine ?—

opposed, the balance is good except for the couple, which it is impossible to reduce below a certain point with this type of engine—hence a good deal of the wobble in a Scott frame.

It is a pity that two-stroke principles do not adapt themselves very readily to multi-cylinder engines, the matter of crank case compression rather upsetting the order of things. One type, however, suggests itself—a vertical three-cylinder two-stroke. Such an engine would be ideal in every respect, equal in balance and torque to a six-cylinder car engine, and its design could be pretty straightforward—a cheaper engine to produce than a three-cylinder four-stroke, and also lighter for the h.p. developed. If fitted with aluminium pistons and steel cylinders it would be readily adaptable for a very speedy solo mount, but of course there is the usual fly in the ointment—lubrication! I rather imagine that the problem of equalising the supply would cause the producer some sleepless nights, and the only method which suggests itself as being the least likely to cause unending trouble is drip feed into the induction pipe. Even then one of the three cylinders would inevitably be nearer the drip than the other two, and would probably take a good deal of the supply intended for its two brothers. Petroil would ensure all three obtaining an equal share, but no one who has tasted petroil likes it.

Those who talk about radials and rotaries for motor cycles are indulging in a flight of fancy, as these two designs may be set down as indicating the height of inadaptability. Already there is enough mud slung about by the wheels, and if a rotary engine joined in, distributing the slush from the front wheel and incidentally throwing in a little oil of its own, we may as well give up all effort at mudguarding. CHINOOK.

THE A.C.U., M.M.D.

An Important Role filled by Volunteer Motor Cyclists.

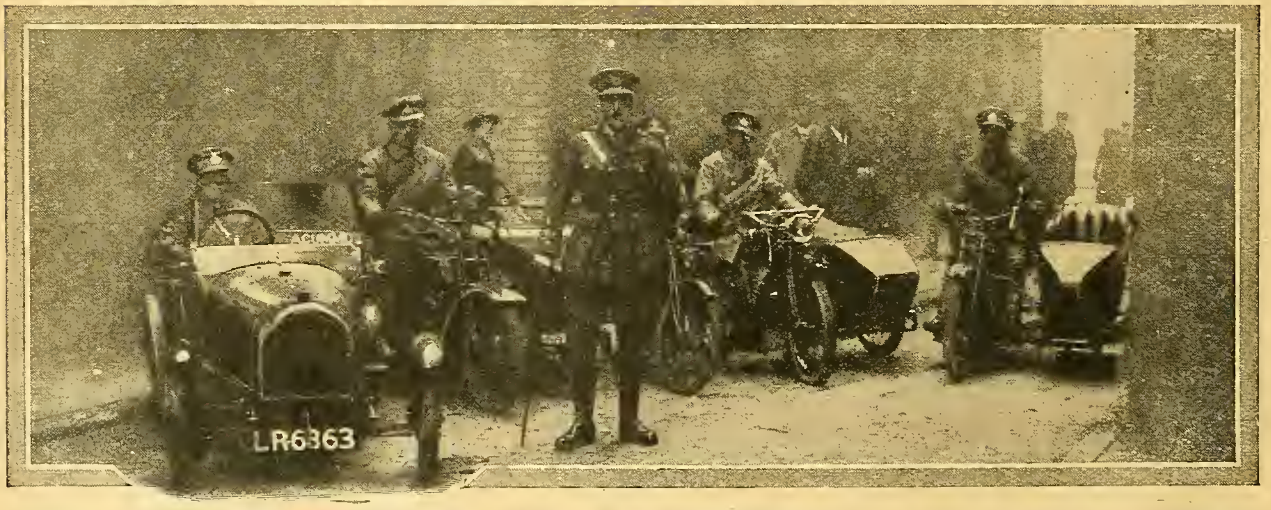
THE first messenger to be despatched on the A.C.U. Motor Messenger Detachment Service was sent away from outside the Central Telegraph Office on the 17th of December by Major T. W. Loughborough, secretary of the Auto Cycle Union, and an official of the G.P.O. at 12.11 p.m. He wore khaki uniform and was riding a 3½ h.p. Sunbeam sidecar combination.

These messengers carry despatch bags on their backs or strapped to their sidecars, in which important despatches are carried between various Government offices. They have a comfortable room in which they may wait at the C.T.O., in which there is a fire, telephone, and some comfortable chairs, while they have free access to the C.T.O. buffet.

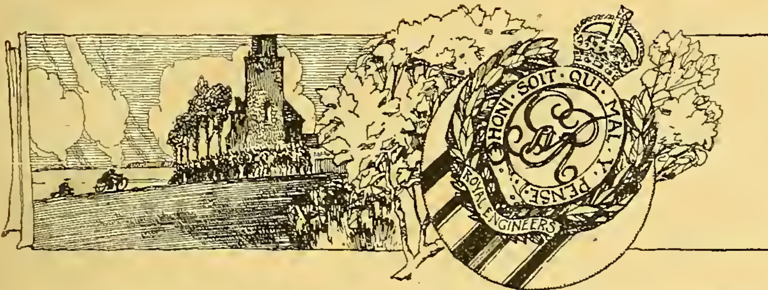
The men work in shifts and depart and arrive to schedule. Each shift is under the charge of a corporal.

Among the machines which were waiting we noticed a 1916 Indian, which looked practically a new machine. Its rider was the second man to be despatched. We also saw a 3½ h.p. twin-cylinder James, fitted with a wonderful array of additional cooling radiators. Over the exhaust valve cap was an aluminium fin cooler, while the two compression taps were screwed into devices of similar pattern but made of brass. There were as well a 2¾ h.p. Douglas, which was ridden by one of the A.C.U. staff who has joined the Service, and a 4 h.p. Douglas fitted with a Euk easy starter and Senspray carburetter. This latter was certainly a very easy starting machine.

The first messenger to be sent off was the only one who had succeeded in obtaining the armlet of the Detachment—a device in red, blue, and yellow—above which is worn the silver-plated badge of the detachment. The first man was unfortunate enough to stop his engine immediately after being sent off, but the delay was of short duration, and he was soon heard speeding his way on his machine.



A group of A.C.U., M.M.D., despatch riders waiting to be sent off. Major Loughborough, secretary of the A.C.U., is seen in the foreground.



HONI SOIT QUI MAL Y PENSE
ROYAL ENGINEERS

MILITARY NOTES.

TANK CORPS WINS ITS FIRST V.C.

THE Tank Corps has got its first V.C. in Act.-Capt. Clement Robertson. Though the *Gazette* does not specifically disclose the fact, there is little doubt that some of the V.C.'s were won in the recent fighting near Cambrai.

Capt. Robertson (a second-lieutenant in the R.W. Surrey Regt.) was deputed to lead the Tanks on foot. The *Gazette* says:

"Capt. Robertson, knowing the risk of the Tanks missing the way, continued to lead them on foot, guiding them carefully and patiently towards their objective, although he must have known that his action would almost inevitably cost him his life.

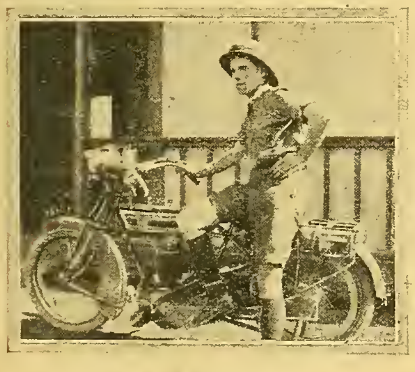
"This gallant officer was killed after his objective had been reached, but his skilful leading had already ensured successful action. His utter disregard of danger and devotion to duty afford an example of outstanding valour."

* * *

INLAND WATERWAYS TRANSPORT.

SPR. H. GIBBS, writing from Mesopotamia, says: "In common with my pals whom you see in the photograph, I have been somewhat disappointed in not seeing any reference to our corps or section of the Army in *The Motor Cycle*. I think there must be quite a number of old motor cyclists out here in this section of the Engineers, although we are now chiefly engaged on water-cooled marine or car engines installed in all kinds of boats. We long for the day when we shall be home again to try the favourite runs. Your mention of 'Ye Stonebridge Hotel' in the article on the Tilston engine brought me very near home—Erdington.

"I am thankful to have got safely through nearly twelve months' service here—chiefly in the workshops. We occasionally get a motor cycle to overhaul."



Sapper H. Gibbs, I.W.T.

THE TRAINING OF WOMEN FOR WIRELESS APPARATUS WORK.

WELL educated women are wanted immediately for training on urgent Government work in connection with wireless apparatus. Candidates must be between 18 and 40 years of age, and prepared to pass a medical examination. The course of instruction will be given in the electrical laboratories at the Polytechnic, Regent Street. During this period a weekly maintenance allowance of 25s. is payable. For further particulars apply Director, Training Section, Ministry of Munitions, 6, Whitehall Gardens, S.W.1.

Cpl. T. W. Parker, A.S.C.,M.T., formerly of *The Motor Cycle* editorial staff, whose interesting letter from Egypt was published in a recent issue.

* * *

KILLED IN ACTION.

ANOTHER motor cyclist who later took up flying has, we regret to say, been killed in action. This is Sec.-Lt. H. S. Holroyde, East Yorkshire Regt. He was educated at Tonbridge and Dulwich, and at the beginning of the war, at the age of sixteen, he joined the Kent Motor Cyclists, and was later transferred to the London Scottish. Subsequently he entered Sandhurst and obtained a commission in the East Yorkshire Regt., being attached to the Royal Flying Corps. On May 10th he was out with five other aeroplanes on a long-distance reconnaissance. They had to fight their way out and back, and just as they turned to come back Lt. Holroyde's machine was hit by one of the hostile aeroplanes, fell out of the formation, and was seen to dive steeply, with smoke issuing from it. A German machine dived down on it, but Lt. Holroyde opened fire and shot it down. Both machines were seen to crash almost in the same field.

* * *

THE LATE P. C. D. DOUGLAS.

IN one of the casualty lists last week we noted, with very great regret, that Acting-Commander P. C. D. Douglas, R.N., had been reported as having died of injuries. Commander Douglas was one of the leading lights of the Public Schools Motor Cycling Club, and performed consistently well in various competitions at Brooklands and elsewhere on a 2¾ h.p. machine bearing the same name as himself.

We crave our readers' indulgence for again calling attention to his history during the present war. Just before hostilities began he met with a severe motor cycle accident through running into a cart in the dark, and injured his leg very badly. He was for about eight weeks in hospital, but as soon as he could hobble about he endeavoured to join up. He used every means in his power to persuade the doctors to pass him as fit, but without success. After much careful thought he endeavoured to deceive one of the recruiting medicos by hiding his limp by entering the consulting room with a sort of swaggering roll. This perhaps succeeded, but when he was called upon to strip the doctor spotted the scar on his leg, and naturally refused to consider him for a moment as being fit to join the Army. He was, however, determined to do some sort of work for his country, so he spent all his available cash in a Talbot landaulet, and, joining the R.A.C. Transport Service as an owner-driver, he became attached to one of the commands, continuing this work until he was quite fit. Then he joined the R.N.A.S., and served with devotion and gallantry until he met his death.

A group of engineers of the Inland Waterways Transport, Mesopotamia, the majority of whom were ardent motor cyclists before war broke out.

,, 9th	4.39 ,,

Lady Motor Cyclists.

Lady motor cyclists supplied by the Women's Legion, of 115, Victoria Street, London, are now being used by the R.F.C. and A.S.C., and are found as useful as the chauffeuses.

Motor Cycles in Valetta.

We recently had a paragraph to the effect that motor cycles were not allowed in the streets of Valetta, Malta. The editor of the *Malta Herald*, however, having taken up the matter with the Lieut.-Governor of the island, permission has now been obtained for the use of motor cycles in the streets of Valetta.

Catching Up the Spark.

One of the brightest Service magazines we have seen is *The Eagle*, which deals with life at a R.N.A.S. land station not a hundred miles from Edinburgh. Replying to a correspondent in trouble with the timing of the magneto on his motor cycle, the editor says: "The fault you describe is evidently due to what is technically termed 'magneto too far advanced'; in other words, the spark occurs before the engine is ready for it. Try running the engine faster, so that it may catch up the spark."

Another Unpublished Query!

An anxious querist recently wrote to us stating that he had a cylinder and piston and wished to build a three-wheeled monocar, would we please tell him how to proceed? The most useful suggestion was, we think, one put forward by the office boy, who overheard the ensuing discussion. "Tell him to scrap the cylinder and start afresh right from the piston as the centre of it all!" As a matter of fact this remark was wiser than its author probably realised, for with the coming of the aluminium piston and the added importance recently attached to piston rings, building your engine round your piston has a significance that a few years ago would have been quite impossible.

Police Intelligence

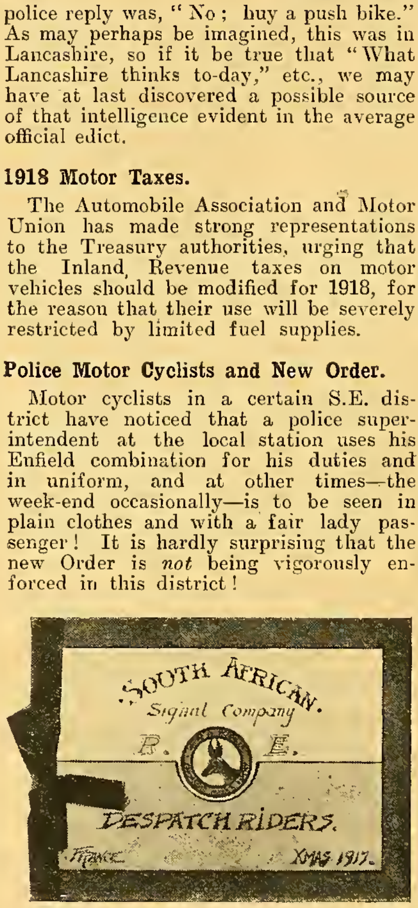
Another querist—one of many hundreds taxing our presumed omniscience in respect to the latest petrol restrictions—tells us that as he wanted to be on the safe side he asked the local police if he could use his sidecar to carry his wife and family to and from the station. The police reply was, "No; buy a push bike." As may perhaps be imagined, this was in Lancashire, so if it be true that "What Lancashire thinks to-day," etc., we may have at last discovered a possible source of that intelligence evident in the average official edict.

1918 Motor Taxes.

The Automobile Association and Motor Union has made strong representations to the Treasury authorities, urging that the Inland Revenue taxes on motor vehicles should be modified for 1918, for the reason that their use will be severely restricted by limited fuel supplies.

Police Motor Cyclists and New Order.

Motor cyclists in a certain S.E. district have noticed that a police superintendent at the local station uses his Enfield combination for his duties and in uniform, and at other times—the week-end occasionally—is to be seen in plain clothes and with a fair lady passenger! It is hardly surprising that the new Order is *not* being vigorously enforced in this district!



SOUTH AFRICAN.
Signal Company
R. E.
DESPATCH RIDERS.
FRANCE XMAS 1917.

Christmas greeting card received from "thirty despatch riders of South Africa XV. Corps, B.E.F., France."

Greetings from Despatch Riders of South Africa.

Among the many greeting cards received from the boys with the various Expeditionary Forces is an amusing one from a Signal Company attached to the R.E.'s, which we reproduce on this page. The inscription reads:

"*Cheerio! Hlala Gahle! Alles Zal recht Komen. Après la Guerre.*"

We're often in the mud,
But never in the dumps:
The country side's aflood,
There are bombs and frightful crumps.

The Boche is not a sport,
He doesn't play fair cricket:
So till he has been taught
We'll simply grouse and stick it.

Special Features.

WHICH TYPE OF MULTI-CYLINDER ENGINE?
FUEL LOSS AT THE CARBURETTER.
COAL GAS IN PRACTICE.

One Way with Trappers.

A motor cyclist, stated to be attached to the R.F.C., summoned at Greenwich for exceeding the speed limit, is stated to have said to the policeman when stopped, "I will see that you get a bomb the next time there is a raid on"!

Shelter Box for Westerham Policemen.

The policeman who daily does point duty at the junction of roads at Keston, on the Westerham Road, is to be provided with a shelter box, on account of the very exposed position. This is one of the most dangerous crossings in outer London, and the constable has averted many a smash, therefore he is certainly deserving of such shelter during the slacker hours of the day.

Motor Cyclist Relieves Food Situation.

Excellent work was done on a sidecarrier in the Cudham district last week. Owing to 4ft. snowdrifts, traffic on the Westerham road was stopped for several days, and residents who rely upon food supplies by road were in an awkward position, the local stores being sold out. Through the narrow cuttings made in the drifts the sidecarrier was able to proceed, making several journeys to and from London with supplies for the shops. Owners of local vans furnished the necessary petrol. In hilly, outlying districts, the sidecarrier clearly has advantages over the four-wheeler, particularly on snow and ice-bound roads.

Industrial Reconstruction Council.

The first meeting of the Industrial Reconstruction Council was held on Tuesday, December 11th, at the Holborn Restaurant. The chair was occupied by the President, Sir Wilfred Stokes, K.B.E., and the Draft Constitution submitted by the Provisional Committee was approved and adopted. Mr. Ben Tillett, M.P., who was one of the speakers, emphasised that the need of the future in any industry was not only efficiency of labour, but efficiency of capital, and Mr. Ernest Benn elaborated the objects of the Council rather more fully. He maintained that it was essential for each trade to have a self-governing body to maintain and develop the trade. The membership of this Industrial Reconstruction Council was to be open to any trade societies, the only necessary qualification being a genuine desire to promote the doctrine of industrial self-government.

Gas-proof Gasbags.

It may be of interest to our readers to know that the gas trailer we have under test is one of the cheaper variety sold by Messrs. Douglas S. Cox, of 6, Lansdown Hill, West Norwood, S.E.27. The "Superflex" container, which costs 20% more than the ordinary pattern, is guaranteed absolutely gastight and to remain fully charged for one week without any appreciable loss. It is further guaranteed for a period of six months.

The New Council.

In discussing the formation of the United Council (referred to in our current leading article), *The Autocar*, in its issue of November 24th, used what strikes us as a very apt metaphor. *The Autocar* said: "The Government has for the last twenty years regarded the motorist as a kind of goose that lays the golden eggs, and the fact that the goose has not been squeezed to death is accounted for more by the robust health of the bird than by any tenderness in its handling on the part of the Government."

Motor Cycling Schoolmaster fined for using Petrol.

At Greenwich, on the 24th ult., a schoolmaster at St. Saviour's Schools, Lewisham, S.E., was summoned for driving a motor cycle at 29 m.p.h. at Catford and also for "unlawfully using petrol." Defendant expressed regret for the first offence and pleaded "Not guilty" to the second.

Mr. Scard (for defendant) stated his client was granted a petrol licence for "the purpose of paying visits to the country and seaside to procure specimens for art and science training." When stopped he was riding to Hayes and Cudham to collect leaves and twigs. It being Sunday, no trains run to Hayes.

For the first offence a 10s. fine was imposed. The other, the magistrate decided, was intentional evasion of the Order. There were other places he could reach by train to collect the specimens. There must be a fine of 40s.

Motor Cycling in Hong Kong.

A report from Hong Kong, a British Colony, states that there has been a considerable increase in the use of motor cycles.

We remind our readers that Hong Kong is a British possession because we are told that practically all the motor cycles used out there are of American manufacture.

The A.C.U.M.M.D.

All through the Christmas week-end the recently installed Auto Cycle Union Motor Messenger Detachment, consisting of motor cyclists bearing important despatches between the C.T.O. and the principal Government buildings, worked without a hitch.

This service is proving itself to be of the greatest value to the country. All vacancies are now filled, but there is a waiting list.

Tyre Mileage.

We learn that a Melbourne motor cyclist has used a 26in. × 3in. white-ribbed cover fitted to the driving wheel of a 6 h.p. twin-cylinder motor cycle over a distance of 8,754 miles on the back wheel. It was then removed to the front wheel, and finished up with a total of 16,842 miles without being retreaded. The rider's weight was 14½ stone, and the machine was a heavy twin. Thus the performance is a meritorious one.

Rubber after the War.

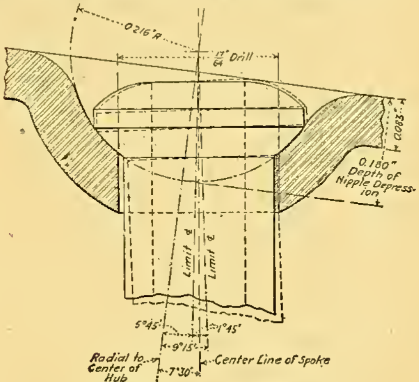
At the present time we are so obsessed by the double questions of fuel and legislation that we are inclined to pay little attention to another very important motoring attribute—rubber. But has any invention done more for the motor than the pneumatic tyre? Apparently America leads the world in the manufacturing aspects of the rubber trade, while England controls the productive aspects of the trade, and it is comforting to learn that after the war the production of tyres is likely to be well ahead of all demands.

A LITTLE HELP IS WORTH A LOT OF PITY.

"Knights of the present day" giving a hand to the owner of an Enfield outfit.

Standardisation of Motor Cycle Rims in America.

As most of our readers will be aware, motor cycle rims were standardised in England some two years ago, this act of standardisation being the result of investigations begun some two or three years earlier—in 1913. In the *Journal of Society of Automotive Engineers* (of America), dated November, 1917, a report is given of a meeting and discussion on the question of standardising not only American motor cycle rims, but also the depression in the rims for spoke nipples. Up to the present the depression in English rims for spoke nipples is left entirely to the maker's option, although some of the largest makers, notably the Dunlop Rubber Co., Ltd., have long been agitating for a standard depression as well as a standard rim. The measurements finally adopted for the depression in the rim are shown in the accompanying illustration, which is reproduced from the journal already quoted.



Motor cycle rim depression.

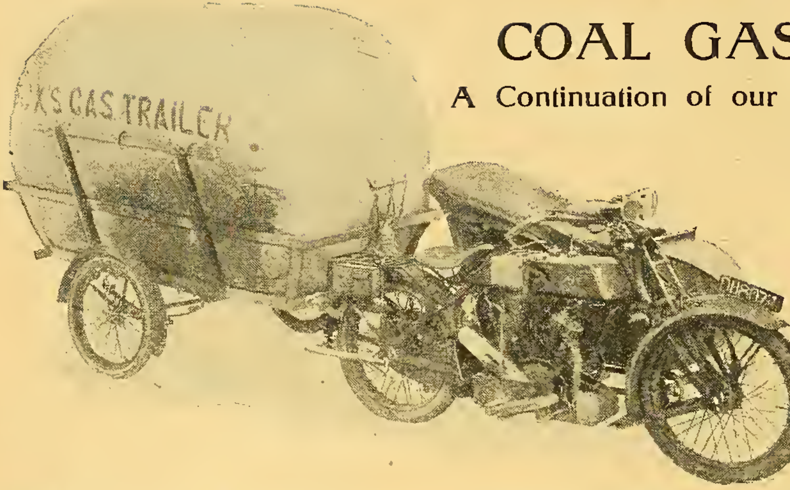
The advantages claimed for this particular depression are that it permits a perfect spherical bearing surface for the nipple when assembled with hubs of various lengths and diameters, and also a standard rim may be used for all motor cycle wheels with this same rim depression.

Motor Cycles in Brazil.

According to the *Motorcycle and Bicycle Illustrated* (U.S.A.), there are very few motor cycles in Brazil, and, moreover, there is no promising market. Bad roads and very high taxation have acted as a very efficient deterrent.

Home-produced Petroleum?

While comment at the present stage would be premature, much motoring interest attaches to a paragraph that appeared in the week-end newspapers concerning the discovery of paraffin in a well at Ramsey (Huntingdon). Two pumps, situated close together, were on Friday found to yield paraffin instead of water, and at the time of writing some 1,500 gallons of oil had been obtained, while the flow showed no signs of ceasing. For some years the water of the well, or wells, has given off a strong smell of paraffin, and a fatty substance has sometimes been seen floating on its surface. This is, however, the first time that the oil has been obtained in such preponderance over the water that it could be used for lamp oil and for fuel in a stationary oil engine.



COAL GAS IN PRACTICE.

A Continuation of our Notes based on the Daily Use of Coal Gas.

THE 6 h.p. A.J.S. motor cycle on which we are conducting our experiments with coal gas is badly in need of decarbonisation. With petrol as fuel a distinct "pink" is emitted with each opening of the throttle, and the condition of things is gradually becoming worse, but with coal gas, on the other hand, a decided improvement is noticeable, owing to the increased compression caused by the deposit. We have, accordingly, adopted a simple method of varying the compression to suit the fuel. For running on petrol a solid brass ring is placed under the exhaust valve caps, the ring being ⅛in. deep, and machined to assure a gastight joint, so that by raising the cap the compression space above the piston of each cylinder is increased in area, thus eliminating the knock. Before switching over to coal gas the rings are removed, and the caps screwed down on their copper and asbestos washers in the ordinary way.

Incidentally these distance pieces are very useful to any rider, as by their use one is enabled to postpone the necessary evil of decarbonising, while they save the engine considerably when a sidecar is occasionally attached to a mount not intended for that purpose.

We should imagine a Scott two-stroke would yield excellent results with coal gas—provided the gauzes were kept perfectly clean so as not to interfere with the volumetric efficiency of the engine.

In muddy weather the gasbag becomes thickly plastered with mud on either side, a constant cascade being thrown by the cycle and sidecar wheels. This accumulation naturally causes excessive chafing of the canvas at the points where it touches the carrier frame, while the repeated saturations will not tend to improve the gas-retaining properties of the fabric. Similarly, the trailer wheel bearings are subjected to an incessant shower during wet weather, and very soon become full of water and grit unless repeatedly packed with grease. We have been compelled to fit both the machine and the trailer with wide mud interceptions, consisting of flaps of linoleum and American cloth, or the life of the gas container would have been a short if merry one. Though these fitments do not improve the appearance of things, one might as well go the whole hog when towing a gas trailer and drop all thoughts of appearance.

A Non-stop Run.

Recently an extended business trip enabled us to test the road capacity of the bag on a non-stop run. We left Coventry with the container fully inflated, and the first ten miles on a good open road with a strong cross wind was covered in twenty minutes, which may be taken as comparing very favourably with petrol. Also very little gas was used.

At this point, however, we were compelled to leave the main road and proceed by little-frequented byways, abnormally heavy with mud deposited by farmers' carts from the fields, and against a powerful wind. Our speed at once dropped down to an average of 20 m.p.h., which may be taken as 5 m.p.h. slower than would have resulted from petrol. Also our consumption went up enormously, and at the end of twenty-three miles it was necessary to recharge the container. This yields a result equivalent to 46 miles per gallon on petrol, while under similar conditions, with that fuel, we have never obtained less than 58 miles per gallon.

Though when running normally the engine does not overheat, its weary flogging becomes somewhat monotonous under continuously perverse conditions. If much gear changing is done the consumption goes up at an alarming rate, and it is found profitable to stick to top gear, for no amount of continued slogging causes the engine to "pink." It will climb almost anything on top gear at its own speed, while the rider can doze in the saddle, unharassed by the necessity for niceties of mixture or delicate fingering of the clutch.

A Starting Tip.

Discounting the equipment necessary for its use, coal gas as a petrol substitute is very much preferable to the paraffin makeshifts, as, given a correct mixture, no difficulty is obtained in starting, and no knocking or other disconcerting symptoms accompany its use. Pressure feed systems will need to be very delicately applied, however, for it is an easy matter when cranking round the engine to flood the cylinders with gas, in which case it is impossible to obtain a start till the engine has been turned over a few times with the exhaust valve lifted and the gas turned off, thus completely getting rid of the old charges. With the container fully inflated and feeding a supply under slight pressure, we have, on many occasions, experienced the utmost difficulty in starting.

GAS FOR MOTOR VEHICLES.

Use for Essential Purposes only.

THE Board of Trade announces that, with the concurrence of the Petroleum Executive, it has been decided that the use of gas for motor vehicles is to be brought under the same regulations and restrictions as the use of motor spirit. It is stated that the reasons for this step are the serious position resulting from the deficiency of tonnage and the probability that circumstances may arise at any time which will require the further reduction of the supplies of petrol available for civilian purposes, and the urgent necessity of reducing to the absolute minimum the expenditure of labour and materials for other than war purposes. Its object is to provide that, to the extent that gas may be available, it shall be used only for essential needs in substitution for petrol, with the object of reducing the consumption of the latter wherever practicable and of conserving stocks.

It is recognised that a certain number of vehicles have already been fitted for the use of gas, and, wherever possible, permits will be granted in these cases to enable such vehicles to be used for essential purposes, as indicated by the Motor Restriction Order. It is not intended to prohibit the use of gas for motor vehicles in so far as, subject to other considerations, it may be available, nor to license the quantity that may be purchased, but only to confine its use to the purposes stated. The best methods of the adaptation of gas for driving motor vehicles and questions relating to the safeguards against any danger attending its use are the subject of investigation by Mr. Walter Long's Committee on Gas Traction.

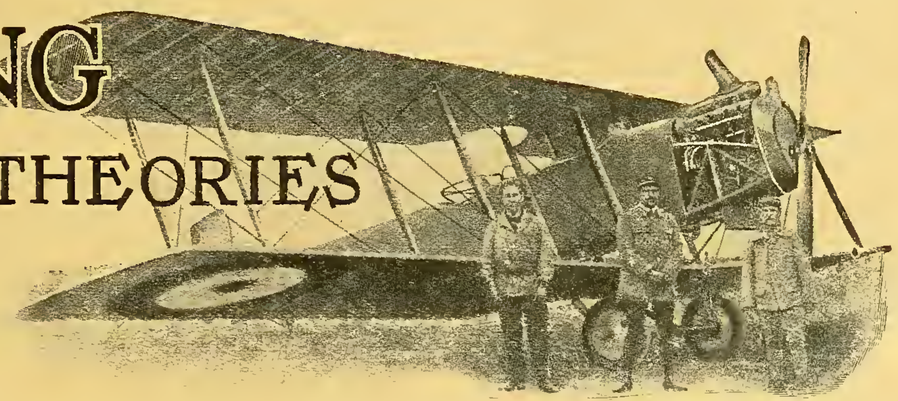
It is proposed to issue shortly a new Order consolidating and amending the present Motor Spirit Restriction Orders, and the regulation of gas will be dealt with in a new Order, also to be issued in due course.

FLYING FACTS AND THEORIES

MORE ABOUT TURNING.

With Special Reference to Some Correspondents.

By W. G. ASTON, A.M.I.A.E.



L'Automobile aux Armées

NOTHING could possibly have been more grateful and comforting to me than the volume of contentious correspondence that my articles on flying have aroused. They were initiated purely for the purpose of imparting information, but they could never have been so informative as the discussions they have set in motion. Not having two separate identities I can only advance one side of an argument at most, and though I try to anticipate any objections that may arise it is obvious that much must be left unsaid. I cannot dot every I and cross every T, otherwise I could never cover any ground at all. This unfortunate fact brings me into opposition with such people as "O.J.F.S.," Lt. R.F.C., who, in *The Motor Cycle* for December 20th pops up with a criticism which bears no resemblance at all to his original attack, but deals with points that he must be perfectly aware I gave the reader the credit for inferring.

First as to the fact that I am not a pilot. I have already expressed my regret at this lamentable state of affairs, and can only say that my disability in this direction is outside of my control. But I repeat, neither my regiment nor my rank has any influence upon facts as facts: they would still be facts even if I were a squadron commander. I disavow any invidious comparisons, but I would remind "O.J.F.S.," etc., that the greatest authority on flight in this country, or in the world, for that matter, is also not a pilot, so that, at all events, I sin in good company.

If a theoretical knowledge is found to be at variance with practice then it is obvious that the theory it endorses must be wrong. But I entirely fail to see in what direction I have been proved wrong; taking one of my sentences away from its context and turning it into a generality which was manifestly never intended by me, does not in the least prove me wrong.

The Loss of Height on Turns.

Take this excerpt, for example, as quoted by "O.J.F.S." "If the throttle is not opened at the moment of making the turn, the machine will lose height." This is not a general truth, but it is perfectly true in regard to the conditions in which the statement was made, namely, if the speed of the machine is kept constant on the turn and during the turn is equal to the previous horizontal speed. I should be sorry even for "O.J.F.S." to think I am so ignorant that I do not know that an aeroplane can climb whilst turning. Further, it is clear that it can do so without the throttle being opened at all, but to do so it must lose speed. If a turn is made without losing either height or speed, such an evolution requires more power from the engine.

Again, if an aeroplane is gliding with the engine cut off it can make a turn and retain its speed only by losing height. Conversely it can make a turn and retain its height only by losing speed. It is merely a case of transforming potential into kinetic energy and *vice versa*. If the machine is doing a very fast glide the excess of kinetic energy it possesses may be sufficient for it not only to retain its height during the turn but actually to gain additional height, but needless to say this requires a corresponding diminution of speed.

Height and speed, within the limits imposed by the minimum and maximum speeds of the aeroplane are always interchangeable, as they represent merely different conditions of energy. If a machine is flying or gliding at its maximum speed it can attain height by losing some of its speed, but it must not lose so much that it gets below its stalling speed. On the other hand, given sufficient height, it can attain its maximum speed by a sacrifice of some of that altitude, but beyond its "limiting speed" it will gain nothing. This, of course, is a very high speed indeed, and is probably never attained in practice.

Air Fighting.

Whether or not an aeroplane has an engine of such power that its speed variation is big, or small, when it makes a turn it is bound to lose something—height or speed, or both, and it can only keep them both constant by making a call on such excess power as the engine possesses. I can hardly think that "O.J.F.S." genuinely failed to credit me with knowledge of this fact. If he did, he appears to have been all alone except for his *confrère* "F.M.C.H." (also Lt. R.F.C.) who took me up on the same point. The latter says, "It is perfectly easy to climb on a turn." Whoever denied it? Not I certainly. But one must concede either a loss of speed, or more power from the engine, nevertheless. "The air fighter . . .," says this officer, "is dodging and twisting all the time. His throttle is used quite a lot as it is, but on every turn! I suppose the sharper the turn the greater the increase." May I again remind "F.M.C.H." that the dodging and twisting air fighter is not maintaining a constant speed by any means, and that my original

Flying Facts and Theories.—

statements were made distinctly on the assumption of such constant speed. If the pilot is content to make his turns at the expense of either height or speed it is clear that he need not bother about his throttle at all. "The sharper the turn the greater the increase (of throttle)! Most decidedly *yes*, "F.M.C.H.," provided, once more, that neither speed nor height be lost.

Mathematical Proofs.

I next have to thank Sec.-Lt. J. H. Gotch, R.F.C., for his most appreciative letter. His explanation of turning "up" and "down" wind is precisely similar in results to mine, though not quite so elementary. I preferred to express myself non-mathematically so as to interest as many people as possible, and if certain pilots, whose railway carriage conversation I have chanced to overhear, were so grossly ignorant as to hug the fallacies I was trying to expose, it was obvious to me that they would understand only the very simplest of arguments. If all readers of *The Motor Cycle* had a sound grounding in elementary physics, most of its technical articles could be condensed to a mere paragraph, and some of its most valuable ones would be rendered entirely superfluous.

I likewise have to express my gratitude to "Commonsense" for his appreciation.

In a long connection with technical journals I have never before come across the type of correspondent typified in "Dyne." Gratuitously to write a second letter on the heels of his first and to admit his mistake was an action which I should say is quite unprecedented. It is quite the greatest compliment I have ever had paid me, and I thank Mr. "Dyne" very much indeed. Most correspondents take a running pot shot at a contributor, and there is always a doubt whether they even see the issue in which he replies to them.

Radial and Rotary Engines.

In answer to L.-Cpl. S. A. Reeve, who has certainly quite justifiable criticisms to offer on my article on radial and rotary engines, may I say that I am perfectly aware that the types of engine I described are more or less out of date, but I was dealing only with broad principles which were just as well illustrated by them as they would be by the latest radial and rotary productions. L.-Cpl. S. A. Reeve is in the Army. So am I. I have been lucky enough to get permission to write these articles, and I am certainly not going to abuse my good fortune by dealing with designs which in everybody's interest should be kept in the dark. There is far too much cackle as it is about the new things that are being made, and I should be the last to flaunt such information about them as I possess in a public newspaper. So for the time being I must be content to appear a little out of date, though sound fundamental principles never can be.

The L.-Cpl. says, "I suppose Mr. Aston is alluding to the stationary radial when he refers to large quantities of unused oil being blown through the exhaust pipe, for up to the present I think there is only one rotary radial engine which has exhaust pipes fitted." The answer is in the negative. Do not let us waste time over obvious trifles. For "pipe" read "valve" if you like. It is in this case a distinction without a difference.

Centrifugal Force.

Getting back to the question of turning an aeroplane, and especially referring to the fact that embryo pilots are impressed by their instructors with the danger of turning down wind close to the ground, there is one point which has escaped all my antagonists. I also left it out of my article because, as far as I am concerned, the space occupied by a contribution is strictly limited, and one cannot deal with all possible aspects of a thing at once.

When an aeroplane turns its weight is virtually increased by its centrifugal force, and since its stalling speed is a function of its loading it is obvious that on a turn this critical speed will be raised. The same thing applies to looping, and especially to very sharp turns, when, of course, the centrifugal force reaches its maximum. Now when a pilot turns down wind, and glances towards the ground, he finds that to keep the position he expected to have relatively to the earth he has got to make a much sharper turn than he intended. Such a turn may be so sharp as to make the machine's stalling speed higher than that at which it is actually trying to fly, with the result that a crash ensues. Such a state of affairs is easily prevented from occurring by an opening of the throttle, but if the engine is failing this safeguard cannot be used. In the case of a pilot turning up wind the danger is just as much present, as such a turn tends to make him underbank. On the other hand, his apparent ground speed is not so high, and this may make the conditions appear easier, though it is, of course, an optical illusion, for the conditions are identical as far as the aeroplane, as an aeroplane, is concerned.

The Feel of the Machine!

One final remark touching upon a last point in "O.J.F.S.'s" letter. He says I "appear ignorant that one turns by the horizon and the feel of the machine, and not by watching the earth, so that a knowledge of the wind is unnecessary." Now, the last sentence might well have been taken as a text for my original article, since without any knowledge of the wind there is obviously no such thing as "up" and "down" wind—the very thing I set out to prove. As to watching the horizon and not watching the earth, which is what the horizon is made of, this seems rather a difficult feat. Next as to the "feel" of the machine, this seems a singularly inexact method of doing things, and what, after all, *is* the "feel of the machine"? Does he refer to the feel of the relative wind against the pilot's face, by any chance? Again, how does one see the horizon when one is in a cloud?

To consult "a series of comic speedometers and protractors to measure his speed and angles" may be beneath "O.J.F.S.'s" dignity, but I would recommend an occasional glance at them in order to see that his "feel" is properly calibrated. No wonder there are crashes!

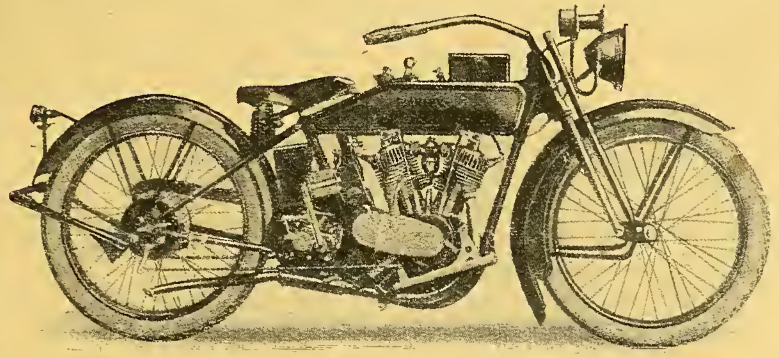
GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

Refinements in the 1918 Harley-Davidson.

Various Improvements in the Power Unit and a Strengthened Frame Construction.



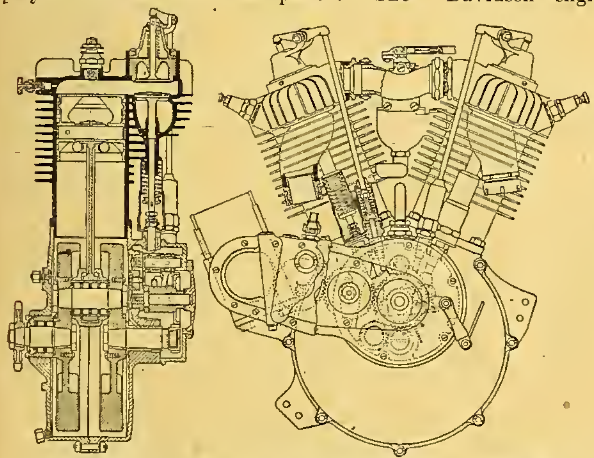
The 1918 Harley-Davidson. So far as the general appearance is concerned no alteration has been made, the improvements consisting of minor refinements.

FOR 1918 the Harley-Davidson Co., of Milwaukee, who are sharing largely in the American Government contract for military motor cycles, have three models to set before the public. These are Model 18E, a single-speed solo mount; 18F, a three-speed model with magneto ignition; and 18J, a three-speed electrically-equipped model. These machines are adaptable either for solo or sidecar use, and it is an interesting point that the Harley - Davidson people have adopted a measure which we have many times recommended to owners of low-powered machines that are put to sidecar use. There is no difference in the Harley-Davidson machines intended for sidecar attachment and those intended for solo use, except that when sidecar requirements are specified, specially stocked distance pieces or joints are fitted between the cylinders and the crank case, so as to reduce the compression.

Power Unit.

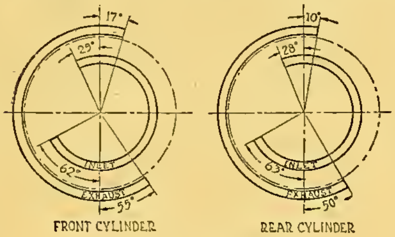
The 45° twin so generally favoured in American practice, on account of the ease with which it can be adapted to a motor cycle frame, is, of course, retained. The cylinders and cylinder heads are in one piece, and very large integral cooling flanges are employed. The exhaust valves are contained in air-cooled pockets, the inlet valves being placed directly above. The cylinders have a bore of $3\frac{5}{16}$in. × $3\frac{1}{2}$in.; cubic capacity, 60.34 cubic inches, which is slightly under the 61 cub. in. capacity (approx. 988 c.c.) set in the States by motor cycling racing rules.

In no particular feature does the engine depart from standard practice. Three rings fairly wide apart are employed in the cast iron piston. The gudgeon pin is more than halfway down the piston, so that the wearing surface is more evenly distributed above and below the pin than is usually the case. The gudgeon pin is secured in the piston by means of a cotter inserted through a hole in the piston skirt.



Sectional view of the Harley-Davidson engine. It will be observed that both plain and roller bearings are used.

A feature of the Harley-Davidson engine is that in its main bearings, including the crank bearing on the driving side, rollers are used. It will be observed that the crank bearing on the timing side is plain, and, with reference to the engine drawings we give, readers will note the neat provision made for enclosing the valve tappets. This system has proved entirely satisfactory, and Harley-Davidson engines are notable for their cleanliness and absence of metallic clatter. The overhead rockers, as hitherto, are left open, the enclosed rocker not having yet come into use in American practice. The big ends are of rather unusual design, one of the connecting rods being yoked, while both bear directly upon the crank pin, instead of one bearing upon the other. The small ends are provided with bronze bushes.



The valve timing.

Valve Mechanism.

The valve mechanism is of special interest. It will be observed that the cams actuate rocker levers provided with cam rollers at their extremities. A peculiar cam contour is employed, giving the unusual valve openings shown in the diagrams. It will be observed further that the diagrams are different for the front and rear cylinders. The inlet valves open gradually, but remain fully open practically to the end of the inlet stroke, whereas the exhaust valves attain their full opening at the beginning of the exhaust stroke, and are very slowly closed. A very considerable overlap is permitted. It will be seen that there are small springs at the lower end of the tappet rods which tend to keep the tappets in contact with the cams.

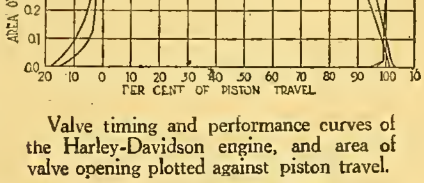
Lubrication.

Except for minor refinements, the mechanical oiling system remains unchanged, the original simple adjustment being provided, while the mechanical pump is assisted by a hand pump on the tank. The oil passes through a small glass sight-feed adjacent to the pump. It is fed to the timing gear case and to the crank case from which the engine is mainly dependent upon splash feed.

Ignition and Timing.

In the magneto models a Berling magneto is used, while in the electrically equipped model the usual American battery system is employed. The generator in these models is a shunt wound machine with automatic control, generating a supply of six volts pressure.

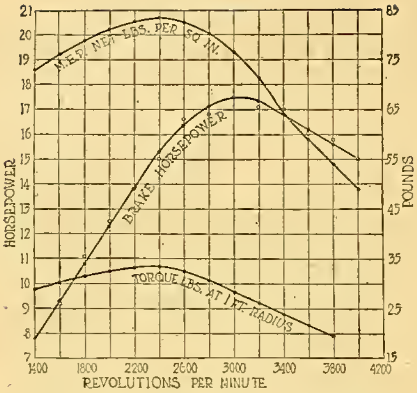
Reverting once more to the valve timing, it is particularly interesting to note that it is unequal for the two cylinders. This is due to the fact that the rocker levers for one cylinder are the reverse of the rocker arms for the other cylinder; thus the valve lift on the front cylinder is somewhat greater than that of the rear cylinder, and the opening period



Valve timing and performance curves of the Harley-Davidson engine, and area of valve opening plotted against piston travel.

Refinements in the 1918 Harley-Davidson.—

is slightly longer. The cams are unsymmetrical, giving a quick opening of the exhaust valve and a quick closing of the inlet. The horse-power, torque, and m.e.p. curves shown herewith were obtained with an engine having this valve setting. The m.e.p. attains a maximum value of 83 lb. per square inch, and at high speed the maximum value is 76 lb. per square inch. The compression ratio is 4.12 to 1, and the valve diameters are 1⅝in. inlet and 1½in. exhaust.



Horse-power, torque, and m.e.p. curves.

Transmission.

As regards the transmission, the clutch lever is interconnected with the gear control, so that it is impossible to shift the gears until the clutch is disengaged. Both ball and roller bearings are used in the transmission, the clutch being mounted on a double roller bearing with a felt ring saturated with oil between the two.

The original Harley-Davidson spring seat-pillar is retained, and, as Harley-Davidson riders know, it is a great acquisition. Such slight frame alterations as have been made tend in the direction of affording greater strength for sidecar use, for which purpose the general layout of the machine is specially suited. It is noticeable, indeed, that the attachment of a sidecar makes no difference to the road speed of the machine.

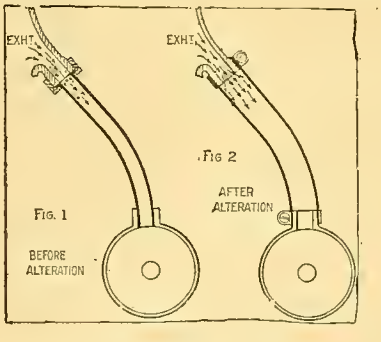
It will be seen from the foregoing that most of the alterations are of a minor description, though they should give greater all-round efficiency in this attractive and sweet-running mount.

IS THE EXHAUST THROTTLED?

A Mysterious Diagnosis of a Baffling Difficulty.

SOME months ago I undertook the job of tuning up a not very ancient 3½ h.p. machine. I quickly got it into a state in which it started easily and ran nicely. It would, however, persist in petering out on hills. I tried plugs and generally recognised ways of remedying this, all with no effect. Eventually, one afternoon, after spending a solid hour in "thinks" over the job, I picked up a brain wave sent out evidently from some high power wireless station—located perhaps in the Coventry district. From whatever source it emanated, its message was plain, though faint at first—"Exhaust pipe" it tapped out repeatedly.

Now the exhaust pipe was clear enough, as I well knew, and the silencer having been recently eviscerated was nothing but a box with holes in it. I could not, however, ignore, a persistent communication of this sort, so I continued to look at the exhaust branch. After a time this is what I saw (fig. 1). I do not know that it is exaggerated, but should it appear so one must put it down to the unusual experience of a brain wave. Fig. 2 will show the alterations made by means of some light piping with saw slots in each end and metal bands for clamps.



Figs. 1 and 2.—Showing the exhaust pipe before and after alteration

The result was all the difference in the world as regards climbing. I could climb my test hill *slowly* and on half throttle, whereas before at whatever speed or throttle I made the attempt I was baulked every time.

Importance of a Clean Exhaust System.

We talk glibly of ample exhaust passages and smooth outlets, and of silencer baffles setting up obstructions, but it will be found on many models that the first constriction occurs at the exhaust pipe, with the consequence that the exhaust is badly throttled, especially at or in the neighbourhood of full load.

Take sketch No. 3. At the time the exhaust valve opens on the power stroke there may be 30 lb. to 40 lb. pressure in the cylinder. This pressure has to fall to atmospheric pressure in 1/150th part of a second if there is to be no excess back pressure when the piston commences its upward stroke (considering engine running at 1,000 r.p.m.) It is of the greatest importance, therefore, that this 30 to 40 lb. should be dissipated *instanter* (or as nearly so as possible). Any obstruction to easy exhaust has immediately two bad effects: (1.) The piston has more negative work to do. (2.) The cylinder gets hotter.

There is something to be said for exhausting directly into a bulb on the cylinder exhaust outlet or for fitting a silencer direct to the cylinder, as shown recently in the case of a small two-stroke engine illustrated in *The Motor Cycle*. This last idea is by no means new. I well remember an old Rex of some thirteen years ago, one of the drop-tail-tank breed which was fitted with a silencer direct on the cylinder. No doubt it is an ugly method, but it ought to be possible to get improved results without a maximum of ugliness.

ENGRO.

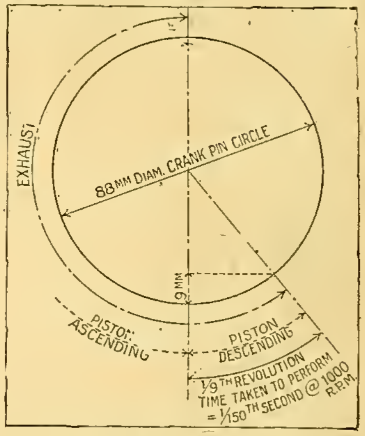


Fig. 3.—Illustrating the short period that occurs to enable the exhaust gases to be expelled.

* * *

A LIGHTWEIGHT RECORD.

AT Seattle recently G. C. Austin started what will probably be the first of a series of twenty-four-hour runs for lightweight machines. Mounted on a Cleveland two-stroke, Austin covered 542 miles in twenty-four hours. His actual riding time was 20h. 26m., and his average speed, therefore, 25⅜ m.p.h.

The course consisted of a round trip of 63.8 miles, which, on the fastest round, was covered in 2h. 10m. Heavy rain, fog, and powerful winds were encountered throughout the trial, the roads for the most part being so slippery that a powerful sidecar outfit was unable to hold the pace. Austin's dry battery lighting installation became "a wet battery," and through most of the night he rode in pitch darkness, assisted occasionally by a hand flashlamp. He states that, given decent luck, he hopes to knock off 700 miles in twenty four hours at an early date.

THE INSTITUTION OF AUTOMOBILE ENGINEERS.

AT the Royal Society of Arts, John Street, Adelphi, W.C., on Jan. 9th, at 8 p.m., Professor Groom will read a paper entitled "The Artificial Seasoning of Wood." Cards of invitation to the meeting may be obtained from the Secretary of the Institution of Automobile Engineers, 28, Victoria Street, Westminster, S.W.1.

RUSHING INTO PATENTS.

A Little Lesson on the Unwisdom of Blindly Patenting any New Idea, with an Example drawn from a Recent Advertisement in "The Motor Cycle."

THE person who will rush into print on the slightest provocation is fairly well known, and, generally speaking, is not altogether regarded as an example to be emulated. The one that rushes into patents on the slightest pretext is a little less common, but is, however, equally liable to create awkward situations and disappointments for others as well as for himself. Many people seem to think that any new idea—that is, an idea that is new to themselves—has only to be patented and their fortune is assured. They do not seem to regard it as essential that their idea should offer distinctive advantages over existing practice, but merely that it should be something new. Even if it be really new, in accordance with their ideas, the possibilities that someone else has previously worked out a similar arrangement never appear to occur to this class of person, and oftentimes a man will spend some considerable time, energy, and money in perfecting an idea, only to find, after his patent has been filed, and sometimes even the article placed on the market, that a prior patent exists.

Examples of this type of occurrence are very numerous in the motor trade, and many a budding inventor has been cruelly disappointed to find that the fruits of his labours have been forestalled, sometimes by a matter of some years. Spring frames especially are a fruitful source of this kind of disappointment, and many ideas have been put on the market for springing, both of motor cycles and of sidecars, only for the inventors to discover that they are infringing someone else's previously-granted patent.

A Startling Advertisement.

The present fuel restrictions have turned many inventive minds to the consideration of possible solutions of the fuel difficulty, and one or two persons of the stamp we have in mind have even gone so far as to patent a recipe for petrol substitute, consisting of such ingredients as methylated spirit, colza oil, and paraffin—a mixture long well known and already worked to death in experimental circles. Similarly, a considerable stir was caused by an advertisement in *The Motor Cycle* of October 11th last of a device by which it was claimed to be possible to run one's motor cycle without petrol or paraffin, and this by means of the employment of a special carburetter. The advertisers of this new device were immediately so inundated with enquiries that it became absolutely impossible to answer them all, and many correspondents wrote to us complaining that one of our advertisers (Messrs. Rogers and Henderson, of Gateshead-on-Tyne) had apparently let them down. Several correspondents had gone to the extent of enclosing cash in letters, but we understand that in every case the money has been returned.

Following our usual practice, we took the first opportunity of interviewing this firm, as ordinary letters and telegrams from us bore no more fruit than those from other correspondents. Our representative who interviewed the firm in question found that the carburetter advertised had not been actually manufactured, but that a patent had been applied for, and that before beginning manufacture the patentees considered it advisable to test the market; consequently the advertisement was inserted in *The Motor Cycle* simply as a feeler to determine which way the wind blew. The result of the advertisement was, of course, only what anyone moving in motor circles at the present time would have expected, and the patentees soon came to the conclusion that to satisfy the enormous demands put upon them they would require extensive plant and considerable capital. This was as much information as our representative could gather, and he did not succeed in getting any particulars of this new device.

The Invention!

Recently, however, owing to some private difficulties, one of the patentees has disclosed to us the nature of this invention, which simply consists of an acetylene generator, the idea being to put on the market a special acetylene generator capable of replacing the ordinary petrol tank and thus enabling acetylene to be used as a fuel!

There is perhaps not a single reader of *The Motor Cycle* who does not know that acetylene has been the subject of experiments as a motor fuel for very many years, and that in spite of research work expended on the subject, no real success has yet attended the attempts. There is, of course, no question whatever about the possibility of acetylene as a fuel. The difficulty arises over its suitability and its convenience, and there is no need to enter here into the various reasons why acetylene has hitherto been discarded as impracticable for all ordinary purposes, and this quite independently of the cost aspect of the question. Moreover, at the present time carbide is unobtainable.

"The inventors" of the device to which we refer were apparently not regular readers of *The Motor Cycle*, and when they found that a motor cycle engine could be made to run on acetylene they considered their discovery to be one of far-reaching importance Hence, it was their intention, after making sure that a market existed for their device, to place this panacea of all evils before the motoring public.

This explanation will perhaps be welcomed by very many of our readers who wrote for particulars immediately this advertisement appeared, and who have had no replies. It also serves to adorn the tale, and to point the moral with which we introduced these remarks.

We cannot do better than reiterate our advice to all inventors that, before they spend money on patenting, or preparing for the manufacture of any of their designs, they should search most conscientiously all possible records to make quite sure that their idea really is new. By adopting such a course they will save themselves from much bitter disappointment.

A SOLDIER-AUTHOR.

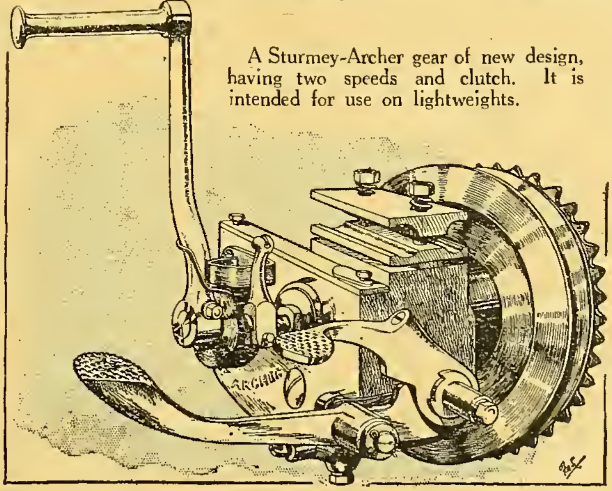
IT is not often that our soldier readers shine in the direction of authorship as well as military prowess. Capt. S. Bramley-Moore, however, has just blossomed out as an author, and a very able one, too. He was one of the very early motor cyclists, and in 1904 was a partner with Frank Hulbert, of the Triumph Cycle Co.

On the outbreak of hostilities, Capt. S. Bramley-Moore joined the A.S.C., and later was awarded the Military Cross.

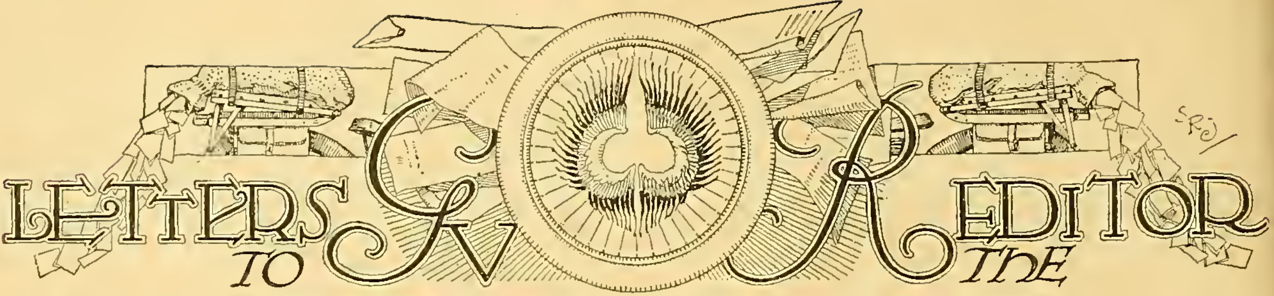
His book is known as "Motors in a Nutshell," and is published at 1s. 6d. by Messrs. E. F. and N. Spon, Ltd., 57, Haymarket, London, S.W.1.

NEW STURMEY-ARCHER TWO-SPEED GEAR.

THE latest production of the Nottingham factory is a young brother of the well-known three-speed gear. It is very similar in details and fittings, but appreciably smaller. Simplicity is its key-note. Gear operations are by two foot levers, giving high, neutral, and low positions. With it is incorporated a cork inset plate clutch, handle-bar controlled, and the usual type of Sturmey-Archer kick-starter. It is now on test by several leading lightweight manufacturers, and should prove as valuable an asset for junior machines as the three-speed gear has proved for the higher powered models. No one will doubt the necessity for a good variable gear on small machines, while the standard three-speed box is on the heavy side.



A Sturmey-Archer gear of new design, having two speeds and clutch. It is intended for use on lightweights.



LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

PETROL WASTE.

Sir,—In your publication of December 27th your correspondent "Economy Officer" evidently does not know what he is talking about when he says, "Incidentally, it may be mentioned that a petrol tin is easily opened without a wire cutter." The petrol tins referred to by "Fair Play" in your issue of November 8th are four-gallon tins (two in a box), soldered top and bottom, with absolutely no opening whatever. I have checked the unloading of thousands.

When the tins are opened at the petrol wharf they are stabbed top and bottom with a kind of dagger.

ONE WHO KNOWS.

TECHNICAL INACCURACY.

Sir,—I do not like to rush into print, but I think I shall not be the only one to protest against the appearance in the premier motor cycling journal of a story called "A Race with Ruin," by Angelina Simpkins. The author may be an expert in the realm of romantic novels, but she would do well in future to steer clear of the pages of a technical journal. Surely Miss Simpkins, however ignorant she may be herself, can find some motor cycling friend to look over her proofs. The tale is a tissue of technical blunders from beginning to end.

I will only quote one statement in support of my remarks: "The bullet struck a sparking plug, and the electricity blew up." Need I say more?

OLD READER.

[We have submitted the above to the author of "A Race with Ruin" who replies as follows.—ED.]

Sir,—I *cannot* understand how people can say such things. "Old Reader" cannot have read many of my works. The ignorance of some people is appalling!

Never in my life have I been attacked for the accuracy of my details. "Old Reader" has not a leg to stand on.

To begin with, I got all the words from a great friend who is in the Flying Corps, and knows *all* about motor cycles. And I have *several* times gone in a sidecar myself. So I should like to ask "Old Reader" if he has ever seen a bullet strike the sparking plug of a hydrostatic turbine? If he has, let him come forward and say what happened. If he has not, how dare he question my conclusions, based on complicated mathematical calculations?

Besides, I am not *Miss* Simpkins at all, and my husband would have something to say, if he were not at the Front—where "Old Reader" perhaps ought to be!

ANGELINA SIMPKINS.

FLYING IN A CURVED PATH.

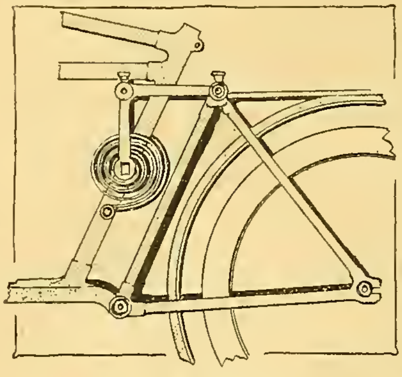
Sir,—I now feel distinctly pleased that I followed my letter of December 6th by a note of retraction, for, by consuming humble pie in this manner, I think I have earned the right to deal exactly as I like with "G.E.H.'s" letter of December 27th. I confess, with sorrow, that, as your correspondent says, much of my letter *was* irrelevant, inasmuch as I could not purge myself of a deplorable spirit of levity that must be wholly abhorrent to a reader of his stern and severely practical temperament. However, I fear that "G.E.H." has rather missed the point of my query. I did not question Mr. Aston's statement, but merely the explanation that was put forward to support it; and it hardly helps me to be informed that the reason *why* an aeroplane requires more power on a curve is that certain specified machines *do* require more power.

Your correspondent asks, "Is 'Dyne' aware that no single force can keep any body travelling in a curved path?" The answer to this question is a most emphatic "No." Because I know of one body—the earth—which is acted on by only one force, the attraction of the sun, and yet this body keeps on steadily lapping round its curved path with undiminished vigour. And there are others. I fancy a great deal of "G.E.H.'s" mystification arises from his failure to distinguish between the forces which propel the body *along* its track and the additional transverse force necessary for converting a rectilinear motion into a curved one. With the first set of forces I was not concerned in the least; my letter dealt solely with the second force, *i.e.*, the force which imparts radial acceleration to the body. In brief, the whole problem is this: An aeroplane requires an additional power output when making a turn, whereas a bicycle or a motor cycle does not. Why is this?

As I have indicated, I believe I am in a position to supply the answer; but, as Mr. Aston will be able to explain the matter much more convincingly and entertainingly than I can, I trust he will find an opportunity of doing so.

DYNE.

REAR SPRINGING.



A suggestion for springing the rear part of a motor cycle frame.

Sir,—I have been much interested in your correspondence *re* rear springing, and cannot resist the temptation of sending you a sketch of what I consider might prove a satisfactory way of solving the problem. Of course, you will recognise it as an attempt to adapt the lever spring principle. I can only say that I never realised what real comfort in a motor car meant until I had these springs put on my old "Merc.," and am longing to obtain something approaching the same luxury on my bicycle.

L.C.E.

PISTON DESIGN IN TWO-STROKE ENGINES.

Sir,—I read with considerable interest an article on the above subject by Mr. James Martin in your issue of December 6th (page 534).

I certainly agree with Mr. Martin's theory that a great deal of piston ring trouble on two-stroke engines would be obviated if the rings were situated in approximately the position shown in his fig. 4.

At the same time, it must be borne in mind that there is a very good reason for the rings to be situated at the top of most two-stroke pistons, viz., in order that the rings may pass the ports at the lowest possible point in the upward stroke, thus forming a gas-tight chamber above the piston, with only the topmost portion of the piston (marked E in fig. 2 of article) above the ports.

In the design shown in Mr. Martin's fig. 4, nearly two-thirds of the piston would have to be above the ports before the part of the cylinder above the piston were gas-tight.

In view of this disadvantage, I do not think Mr. Martin's suggested piston would prove a success.

D. J. McDOUGALL.

GOODS MADE IN GERMANY!

Sir,—I was very much pleased to see a protest in a letter in this weeks Motor Cycle against your paper taking to put Politics in it such as your advert re (Goods made in Germany). now I am a strong believer in always giving honour to where it is due, what ever the make of a article is, and I call the Paris Resolution nothing but one to keep hatred up, and I think a paper like yours which is for sport should keep clear of such, as a sporting paper, and I am not writing this letter just for myself but on behalf of a good few motorists. we are on the same mind as Mr. Ives that if your proprietors keep this up, we shall stop taking the Motor Cycle which we would be sorry to part with as we all are old readers. F. JONES.

[Naturally we do not agree with the views expressed above, but, as we wish to give all sides a fair hearing, we publish our correspondent's letter *exactly* as received.—ED.]

Sir,—I was greatly disgusted to read Mr. C. S. Ives's letter in your issue of the 13th December.

According to his ideas we should welcome the unspeakable Hun with open arms and purses directly peace is declared. I should like Mr. Ives to have been with me recently when I inspected a merchant ship that had been torpedoed without warning. I was shown two caps—all that was found of the two firemen on duty. Are we to forget this sort of thing at once?

Personally I shall never shake hands or do business with a German as long as I live. LESLIE S. BROAD.

Sir,—I heartily endorse the remarks of Mr. Chas. S. Ives in your issue of December 13th, as I also feel that the notice which you print weekly is unworthy of a sporting paper. Are we to allow the present bitterness and the horrors inseparable from all wars to make us forget the part played by the Bosch magneto in the development of the petrol motor? Let us show that we have no eternal quarrel with the Germans, who are the first victims of that Prussianism which now seeks to dominate Europe.

Chelsea. R.O.W.

Sir,—Seeing in your most excellent paper the letter of Mr. Maurice Little sticking up for Mr. Chas. S. Ives, I cannot help writing this letter to express my disgust that any man calling himself an Englishman (perhaps he does not!) should have the face to uphold and encourage German trade in England now or after the war.

Hoping this will find its way to your columns, and so catch the eye of Mr. Maurice Little, and wishing your paper and yourself the best of luck, OLE BILL.

Southampton.

CENTRIFUGAL FORCE.

Sir,—*Re* a letter which appeared in your issue of the 13th ult., under the heading of "Centrifugal Force," "Lieut. R.F.A." apparently sets out to prove that centrifugal force does not act radially. Twice he remarks, "If centrifugal force acted radially." I have always been taught that the force does act radially. If not, how can one account for the tension on a string to which is fastened a body which has circular motion? Surely the force acting as an equal, and opposite, force to the pull on the string is centrifugal force.

"Lieut. R.F.A." also mentions the case of a rider travelling in a straight line, which he counts as an infinite circle, and states that the centrifugal force, if it acted radially, would cause the rider to be immediately thrown over. Assuming the rider travelling in a straight line, and the centrifugal force acting in a direction to his right, then the centre about which he revolves is to his left; but are we not equally entitled to assume the centrifugal force to be acting in a direction to his left, and the centre about which he revolves to be to his right? The two forces would then be equal and opposite, and the rider would not be thrown over. So that certainly will not be sufficient to prove that centrifugal force does not act radially.

Invergordon. SAPPER J.P.D.

Sir,—Your correspondent, "Lieut. R.F.C.," states that what is commonly known as centrifugal force acts tangentially and not radially. May I be allowed to prove the contrary.

Referring to fig. 1, C is the motor cyclist travelling round a curve of radius R at a velocity v f.p.s. His acceleration, as proved in any elementary book on dynamics is $\frac{v^2}{R}$ towards the centre of the curve, and in order to give him this acceleration a force must act in the same direction, and is equal to $\frac{W\,v^2}{g\,R}$, where W is the weight of the machine and rider. This is the centrifugal force. But since to every action there must be an equal and opposite reaction, there must be a force $\frac{W\,v^2}{g\,R}$ acting through the centre of gravity of the machine in the direction C O. This is sometimes known as the centripetal force. So that, in fig. 2, if A G is the motor cyclist and G is his centre of gravity we have a force $P = \frac{W\,v^2}{g\,R}$ acting through G away from the centre of the curve. The centrifugal force is given by the friction of the road Q. Thus, we have a couple tending to turn the machine over outwards, and this must be balanced by another couple of equal moment, which is produced by the weight of the man W acting through G and the vertical component of the reaction of the road, which is also W, acting through A; and in order that this couple may have a moment in the right direction the machine must lean inwards. From this we see that the propelling force does not enter into the question at all, and has nothing to do with centrifugal force as "Lieut. R.F.A." asserts.

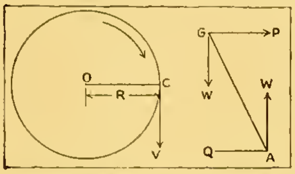


Diagram illustrating centrifugal force.

In the case of a machine travelling in a straight line the centripetal force, and, therefore, the centrifugal force, is $\frac{W\,v^2}{g\,R} = 0$, for R is infinite, if we assume that a straight line is part of the circumference of an infinite circle.

Colchester. E.D.A.

FLYING FACTS AND THEORIES.

Sir,—I need hardly say that the articles which have recently been appearing in your journal from the pen of Mr. W. G. Aston supply a long-felt want, namely, at least an elementary knowledge of the principles of aviation. The ignorance of the man in the street concerning the reasons why aeroplanes fly is not by any means removed by the exaggerated sketches and explanations vouchsafed by the aviation experts of the daily papers, and it is well that a technical journal of proved authority has stepped in to fill the breach.

In your issue of December 6th a letter appears from "Dyne," the argument of which is, to say the least of it, feeble. If "Dyne" had spent as much time in thinking over his point as he seems to have done in elaborating his powers of sarcasm, one can hardly imagine that he would have written as he has done. His point is that the extra power required by an aeroplane when turning to maintain its altitude unchanged is not, as Mr. Aston said, to supply the force which deflects the machine from its straight path, but to overcome the additional head resistance due to the altered disposition of the wings and rudder of the aeroplane. It is doubtful whether a difference exists between Mr. Aston's phrase and that of "Dyne," and, in any case, it is useless to wave "a particularly large and prominently displayed flag of truce" in indicating it. Such a letter only draws attention to the writer's want of knowledge, not only in actual flying, but also in the theory of flight. [See second letter from "Dyne," December 13th.—ED.]

In a letter from Mr. A. E. Brittain, R.F.C., in the same issue, the question of terms again crops up. He says that "a machine must 'meet' the wind to enable it to sustain itself." I agree with him that unless the propeller thrust causes the air to impart a definite amount of positive and negative pressure to the wings the machine cannot maintain a definite altitude, but whether this imparting of pressure by the air is necessarily "meeting the wind" is a matter of a term. We speak of a calm day, and flight is perfectly possible in a calm. What, therefore, does "wind" exactly mean? P. W. F. MILLS, R.N.A.S.

SPONTANEOUS IGNITION.

Sir,—The figures given under the above title in *The Motor Cycle* of December 13th are very interesting, but would perhaps be better understood if some additional data were given. In column 2 it says, "Spontaneous ignition temperature in oxygen." Does this mean that oxygen only was mixed with the fuel to form the explosive mixture? Was any other gas, inert or neutral, present? Also in the experiments what were the actual compressions corresponding to the ignition temperatures given? It is necessary that we should know these things in order to make a proper comparison with what goes on in a motor cycle engine.

The following particulars are taken from a recent publication:

Fuel.	Compression lb. per sq. in.	Initial temperature before compression.	Temperature of ignition.
Petrol ...	90 ...	364° F. ...	986° F.
Alcohol ...	180 ...	373° F. ...	1,292° F.

These figures show the auto-ignition temperature of the mixture as 986° F. They also show that a compression of even 90 lb. per square inch is not permissible if the initial temperature of the mixture before compression exceeds 364° F. This is the reason that in practical motor cycling with an engine which is inherently given to running hot, even when extra precautions for preventing overheating have been taken, the only remedy left is to lower compression.

The temperatures given in the table do not appear to agree exactly with those of "P.J.M."—there may be an adequate explanation of this apparent difference—but they would seem to correspond to the actual temperatures which do obtain in a motor cycle engine.

It is suggested by "P.J.M." that advantage has not been taken of the properties of certain fuels in order to make up substitutes. This may be so in this country probably because the constituents or ingredients have been difficult to obtain since the war, and it is only since the war that the substitute question became acute. The suggested method of mixtures, I think, has been in vogue in America some time. In order to give *good results* it would seem that any mixture of the sort would only have to contain a small proportion of, say, paraffin or similar low temperature ignition stuff. One would gather that the auto-ignition temperature of a mixture is likely to be governed by the ignition temperature of that constituent which by itself has the lowest ignition temperature. If a list of the ignition points of various fuel mixtures could have been included in the table given by "P.J.M." it would have been of very great interest.

Another point is worth considering, and perhaps "P.J.M." or the writer of the article on "The Chemistry of the Internal Combustion Engine" may be able to throw some light on it. In recent times we have heard a good deal of the process of obtaining light hydrocarbons known as "cracking."

In a very hot engine it seems likely that under certain conditions and with certain fuels there is actually a process of dissociation or "cracking" taking place. A light and readily ignited hydrocarbon may be given off and a carbonaceous residue be left. The former would tend to cause pre-ignition, and the latter, by being deposited in the interior of the engine, to augment the danger. May not this be one of the processes by which the phenomenon of "knocking" occurs?

C.R.E.

A SPORTING CHALLENGE.

Sir,—On opening *The Motor Cycle* of November 22nd, the replies of "Despatch Rider" and "D.R.C." to "M.B., Ch.B.," immediately struck my eye. They are interesting and somewhat amusing.

Firstly let me say that I know "M.B., Ch.B.," very well indeed, and if "Despatch Rider" and "D.R.C." knew whom they were criticising they would be more careful. "M.B., Ch.B.'s" old Brooklands Norton, together with another of the same, has many a time had the supreme pleasure of showing a dusty mudguard to sundry 7.9 h.p. twins. "M.B., Ch.B.'s" criticism (admittedly rather harsh) of the W.D. Triumph was based on the machine's behaviour in France. From experience myself out there, I must say the machine in question is reliable and steady, but slow. Many D.R.'s in the Ypres salient will probably remember one "Stiffy" by name. It passed many, was considered very fast, but would not stand up to a long blind, and was prone to the "drying up" fault. By the way, have "Despatch Rider" and "D.R.C." been in France?

Glasgow. "STIFFY'S" MASTER.

Sir,—As a very old reader of your paper I have been very interested in the correspondence *re* "A Sporting Challenge," and especially with Mr. Houlding's letter, with which I thoroughly agree.

I happen to be one of the "boys" he mentions, and I should be delighted to have the opportunity of putting my short-coupled model K Harley against any 8 h.p. 85×85½ side valve J.A.P. as soon as conditions permit.

I, too, have had great experience with W.D. cycles of all makes, and for nearly two years was a tester at the A.S.C. shop you described in your issue of November 22nd.

All I can say of the speed of the W.D. Triumph is that it is a pity some of us cannot meet those riders who get the remarkable speeds mentioned in your columns; then we should either learn something to our advantage or have a good laugh. From my experience of these machines I should say the latter.

No doubt a good many at home think that, because the Triumph is used by the Army in large numbers, it is "it." What is the matter with the military model Norton and other well-known singles, which, given the opportunity, could do all the Triumph has done?

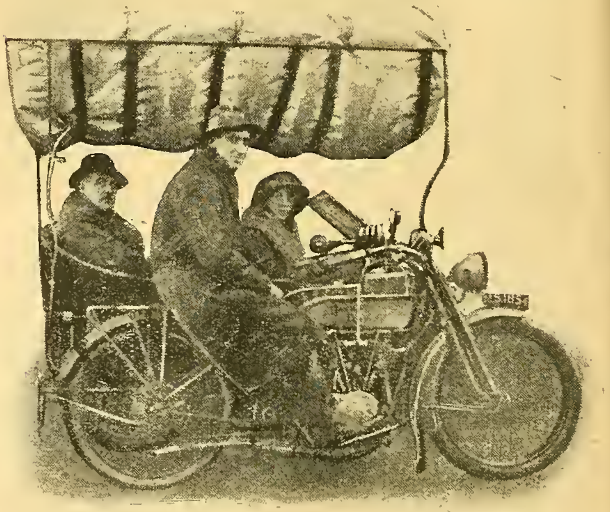
It should be remembered that a good many riders of W.D. machines have had very little experience; in fact, some ought not to be allowed on the road. This the fitters in the shops know to their cost. It is this type of rider who boasts in cafés at night of the speeds he has done, but who, when asked to come out and show what he can do, generally makes excuses about his tyres, etc. This sort of thing does not help to get the perfect motor cycle, and that is what we want.

S. A. MARKS.

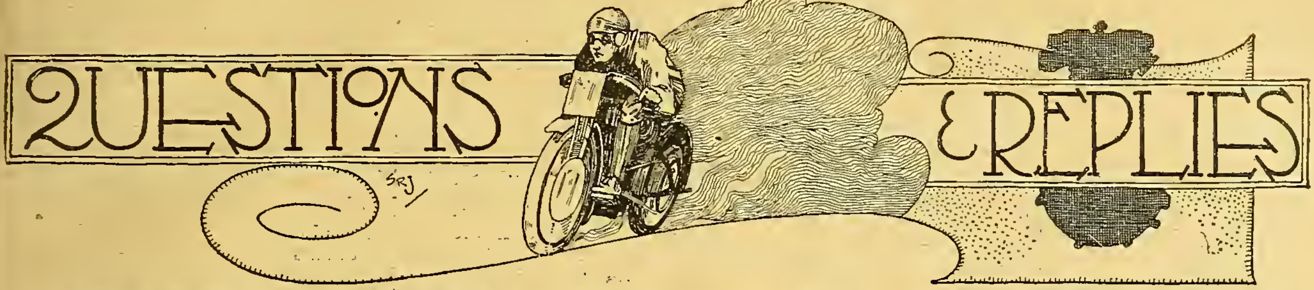
RUNNING ON COAL GAS.

Sir,—I am forwarding a photograph which, I think, will interest you. The machine is a 1915 Harley-Davidson with a 1917 Phœnix double-seated sidecar. The gasbag was made by Barton Bros., and holds approximately fifty-five cubic feet at .2 lb. pressure, which on ordinary roads carries me fully fourteen miles. The bag is supported by a light metal frame slung on cabinetmakers' straps. The closer you get the gas connection to the cylinders the better, as I tried several experiments of putting the gas in through the automatic air intake and also through the hot air intake, but the results were very indifferent. In this instance I was carrying 34 stone, and could surmount without difficulty anything but a freak hill.

JAS. A. TAIT.



A gasbag fitted to a 1915 Harley-Davidson. This holder contains sufficient gas to run fourteen miles.



QUESTIONS & REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

The Lubrication of Chains.

What is the best thing to do with chain transmission having the rear chain exposed? Some people advocate leaving the chain dry, and say that greasing the chain only picks up the dust and grit; but others are all for lubrication. Personally, I find if the chain is greased it requires far more attention than otherwise, but would like to know which treatment is the best.—A.G.C.

After washing thoroughly in paraffin soak the chain in hot blacklead and tallow, heated over a dull fire, then hang up to drain while still hot. A dressing of this sort will last several hundred miles. It is a good plain always to keep the chain dry, never applying thin oil, which merely collects grit, which wears the sprockets and the rollers, and is flung off on to rider and machine.

Magneto Trouble.

I have a 3½ h.p. motor cycle, which I have just overhauled. To test the spark, I fixed a handle on the pulley nut of the engine, and by turning the engine, say, about 30 r.p.m., I got a good spark with the lever advanced, but when I retard the ignition I get no spark at this speed. Would you be kind enough to tell me if there is any fault in the magneto?—C.Y.

We do not think that the magneto is necessarily at fault. The number of revolutions is comparatively low, and probably if you can obtain a speed of, say, 200 or 300 r.p.m. you will find that the magneto will give quite a satisfactory spark with the lever retarded, provided the contact breaker mechanism is not unduly worn, thus causing erratic breaking of the points at the fully retarded position.

The Use of Petrol.

(1.) I have a little petrol. Am I allowed to ride my motor cycle to the station (two miles), using that petrol? I have no petrol licence. (2.) I have a two-stroke fitted with petroil lubrication. I wish to run it on gas. How can I manage about the lubrication? (3.) Will it hurt the engine if I run it with a slightly loose gudgeon pin?—R.H.R.

(1.) If the petrol you have by you was purchased under a motor spirit licence, you may use that petrol for the purposes mentioned in the Motor Spirit Restriction Order, which appeared in *The Motor Cycle* of October 18th. You may use the machine for going to a station if there is no other means of conveyance. (2.) You would have to have a separate drip feed arrangement to bring the oil into the inlet pipe or into the crank case. (3.) It is not advisable to run with a loose gudgeon pin. This should be seen to at the earliest posible moment, though it is not so likely to injure your two-stroke engine as the same defect would be to injure a four-stroke.

Running a Stationary Engine.

I have great difficulty in starting on heavy fuel an old motor cycle engine which runs my workshop. Will you therefore please tell me: (1.) Whether I can obtain without licence or restriction some fuel on which the engine will start easily? (2.) If not, can I obtain an easy start on, say, paraffin? (3.) Is there any likelihood of obtaining a petrol licence for about half or one gallon per month for the above purpose? (4.) As a last resource, how would a small tank do to hold about four cubic feet of gas at four atmospheres for starting? Would it contain enough coal gas for one start and warm the engine up enough to run on neat paraffin?—W.H.L.

(1-3.) As the engine is to be used for stationary purposes in connection with, we presume, some industry, we think you might be quite well allotted a small supply of petrol if you make application to the Petrol Controller's Department, 19, Berkeley Street, London, W.1. We know of no other fuel which you could conveniently use, except coal gas. If this is available it should do quite well. You might try the effect of pouring boiling water over the induction pipe when trying to start on paraffin. (4.) If you have gas laid on there would be no need to fit the tank you have designed, as it could be coupled up direct from the gas pipe to the engine. Provided you get the right mixture (about seven parts air to one of gas) you should start without difficulty. If you cannot get gas laid on, the small pressure tank would do what you require.

In submitting to the Editor articles, photographs, or drawings, contributors are asked to mention whether the illustrations are exclusive, and further to enclose a stamped addressed envelope for return of unaccepted contributions.

A Leaky Oil Release.

Will you kindly give me your advice upon the following point: I have an old type 2½ h.p. engine, and having dismantled it I found that a cork was inserted in the crank case compression release. The cork completely blocked the passage round the central pipe, leaving only the pipe open communicating with the crank case. Should the passage be free? How is this type of release supposed to act? It has always sprayed oil very liberally over my right boot. What can you suggest to stop this, as the outside of the crank case soon gets smothered with oil from the release?—E.T.

We should not think that the cork in question did any harm. It was probably inserted to prevent an excessive amount of oil being blown out of the crank case. The working of the device is exceedingly simple. What happens is that when there is compression in the crank case the air is allowed to escape through the valve, thus creating a partial vacuum during the ascending stroke of the piston. The best way to stop the oil reaching your boot is to fit a long pipe to the exit so that the oil is conducted clear away. Evidently the former owner's attempt to stop the leakage of oil was not successful.

Repairing a Small Hole in the Cylinder.

The cylinder of my B.S.A. machine has developed a very tiny hole. The hole is so small that it does not interfere enough with the compression to prevent my using the machine. My trouble is an oily cylinder. In looking through past numbers of *The Motor Cycle* I find that iron cement is recommended for such trouble. I have asked at different motor cycle shops, and no one has heard of the cement. Will you be so kind as to inform me if it will meet my requirements, and where it can be bought?—E.H.

We should hardly recommend iron cement for a repair of this kind, but should advise you to plug the hole, say, with a brass pin, and see that it is quite smooth inside. Iron cement can be obtained from most leading accessory dealers, such as Brown Bros., Ltd., 15, Newman Street, Oxford Street, W.1; G. T. Riches and Co., Ltd., 19, Store Street, Tottenham Court Road, W.C.2; H. Taylor and Co., Ltd., 21a, Store Street, Tottenham Court Road, W.C.2; R. Melhuish, Fetter Lane; or Geo. Adams, High Holborn.

Local Taxation Licence Exemption.

The Petrol Committee is now issuing petrol licences for trade purposes only. I am the holder of one of these, and use my motor cycle for trade only. Can I run it without sidecar, etc., without taking out a £1 licence? I have read in your columns that it can be done if a sidecar is attached.—F.J.D.

Unfortunately, the authorities will not recognise a solo machine as one which can be exempt from the local taxation licence, as it is not a vehicle constructed and adapted solely for the conveyance of goods and merchandise.

Curious Magneto Trouble.

A magneto on a friend's machine gave out. A new condenser was fitted and a good spark obtained. It sparked well when fitted until the chain was connected to the engine, whereupon no spark could be obtained. On taking the chain off the engine sprocket and still leaving it on magneto sprocket, and turning magneto, with chain held in one's fingers, the spark again occurred, but on recoupling to engine it disappeared. We have not been able to get to the bottom of the trouble, and should be glad of your expert opinion.—R.J.R.

From the symptoms you describe we should imagine that the spindle flange is loose, or the bearings worn, and, consequently, when the chain is fitted to both engine and magneto spocket the pull is sufficient to draw the armature into contact with the magnets. Make sure that the magneto is not rusty inside.

Fitting a New Piston.

I have recently had my 5-6 h.p. Rudge cylinder refitted with a new piston. The firm which did the work were asked by me when I sent my cylinder and piston ring and gudgeon pin to return the Rudge piston, ring, and gudgeon pin as I was only sending them for a pattern. Instead of fitting a Rudge pattern piston, etc., they fitted a two-ring piston with solid gudgeon pin, which is half a pound heavier than the old one. Also, the gudgeon pin in the piston they sent was too large in diameter to go into the small end of the connecting rod of the engine when the rollers are in place. (1.) Apart from the misfit of the gudgeon pin, would the half-pound extra weight upset the balance of the engine? (2.) Is it bad practice to protect the ends of gudgeon pin with brass discs? The gudgeon pin is a driving fit. (3.) Is $\frac{1}{32}$in. play too much for a new piston? (4.) Would two rings double the friction between the piston and cylinder compared with the Rudge single ring piston?—A.H.B.

(1.) The extra weight would upset the balance of the engine rather considerably, but the flywheels might be rebalanced. (2.) No; this is quite a common practice, and is satisfactory. (3.) One-thirty-second of an inch play is too much. The clearance should not exceed $\frac{3}{1000}$in. at the base. (4.) Two rings would not cause much extra friction, and the addition need not be taken into account.

Knocking.

I have a 1916 7-9 h.p. twin which has a bad knock. It sounds as if there were play on a small end or a slack gudgeon pin. The engine was taken down and cleaned, and the connecting rod bearings were all in good condition and the gudgeon pins all right. On putting the engine together again I find the knock is still there. It occurs either on the level or uphill until the engine has reached about half speed on all gears, and then the noise deadens the knock. I am running on half naphtha and half petrol, with a Binks carburetter and hot air intake. There are no air leaks, and it does not seem to be an ignition knock. There is a small crack in the exhaust valve seat of the front cylinder, which evidently causes the valve to overheat. Do you think this might be the cause of the knock?—J.M.S.

The noise is possibly what is known as "piston tap," which cannot be eradicated in engines of certain design, or it may be merely the clatter of the valves or a tappet that requires adjustment. The crack in the exhaust valve seating should be welded, but would not cause this defect.

Engine Racing.

(1.) I have a $3\frac{1}{2}$ h.p. 1917 Rudge-Multi which ran quite well until a few weeks ago. The engine now races madly as soon as the throttle is opened to any extent. Having tightened the clutch, I found a decided improvement when the machine was running, but it is not to my satisfaction. When the engine is running free it seems to do three or four (probably more) revs. per second more than it used to. When the throttle is fully opened the engine turns over so rapidly that it makes me feel nervous. Starting is very hard (almost impossible) until a pumpful of petrol has been injected into the sparking plug holes. When once warm starting is quite easy. The engine also gets over-heated, and knocks when turning corners. The compression is good. (2.) What is a two-stroke? (3.) Is my machine a two-stroke? (4.) Am I likely to get into trouble if I take the machine out to get it into running order? I wish to join a volunteer corps, but cannot do this unless I know that my machine is in good trim.—E.W.B.

(1.) The symptoms described seem to indicate that the engine is running on too weak a mixture. This would account for the difficult starting and for the fact that the engine knocks when trying to pick up. Are you sure that there is not an excess of carbon deposit? Possibly a slightly larger jet would be of assistance to you. Make sure that all the carburetter joints are drawn tightly up, permitting no air leak. (2.) A two-stroke engine is an engine that has a firing stroke every two strokes, *i.e.*, every revolution: see "Motor Cycles and How to Manage Them," obtainable from these offices, price 1s. 10d. post free. (3.) Your machine is a four-stroke. (4.) We do not think so. It all depends upon the view taken of the matter by the local police.

Making an Oiltight Joint.

I have lately dismantled my $2\frac{3}{4}$ h.p. 1913 Ilkston engine for a general inspection and overhaul. (1.) I am rather uncertain as to the best solution with which to make a good crank case joint. Would you advise seccotine or gold size? (2.) Also would you kindly tell me how much oil to put in the crank case before starting up? I should think about a teacupful, but would be glad to have your opinion. (3.) Should I pack the crank case ball bearings with grease or would oil be thick enough, and would you advise a small quantity of graphite if I use grease?—H.G.P.

(1.) Seccotine would make a good joint, as also would fish glue, but a well-fitting joint should not need any external treatment; it should be quite oil-tight. (2.) About three pumpfuls, which should be equivalent to the contents of a small teacup. (3.) You need not pack the ball bearings with grease—sufficient oil will reach them from the engine. On no account use graphite with ball or roller bearings.

The Carriage of Motor Cycles by Rail.

I have bought and paid for an A.J.S. and sidecar. It is at Reading. The vendor informs me that it is not now permissible for it to be sent per passenger train as such goods are not being accepted. Is his statement correct concerning passenger train traffic? I belong to the local motor volunteers, and am very much handicapped by the non-delivery of the machine. The only solution I can think of is to go myself to Reading and ride back. The objection to this is that it would take two days, which I cannot spare. I suggested to the vendor he should meet me, say, half-way, so that I could do the return journey in one day, but he is debarred from riding by the petrol regulations. Can you give any suggestion as to how I may get the machine?—C.F.R.

We have consulted with the Railway Clearing House on the matter, and they inform us that they are unaware of any such regulation, except that motor cycles would not be carried between December 17th and December 28th. What has probably happened at Reading is that there is a great congestion of goods to be carried at the present time on the railway, and the machine has to await its turn. An alternative would be for you to write to the vendor and suggest that he should obtain a permit from the Petrol Controller's Department, 19, Berkeley Street, London, W.1, to deliver the machine, and should then meet you half-way.

RECOMMENDED ROUTES.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

AUTO-WHEEL, only run 70 miles, £10/10; another, good order, £6.—Proctor, Wendover, Bucks. [2425

Bradbury.

3h.p. Bradbury, Simms-Bosch, B. and B., good tyres and belt, perfect working order; £8.—Hanson, Rehoboth, Spring Terrace, Rawtenstall. [X0145

Brown.

BROWN, 3½h.p., mag. ignition, low built, engine lately overhauled, splendid order throughout; bargain, £12/12.—Box L5,317, c/o *The Motor Cycle*. [2514

B.S.A.

B.S.A., 1916, 4¼h.p., 3-speed, chain-cum-belt, C.B. sidecar; great bargain, 45 gns.—12, Crosby Terrace, Long Lane, East Finchley. [2501

1915 B.S.A. Model K, Canoelet sidecar, large P. and H. lamp, sidecar lamp, Lucas horn; £50.—Walbro Cycle Co., Saffron Walden. [X0151

GENUINE Bargain.—1914 B.S.A. countershaft combination, fully equipped, excellent condition; 39 gns.—Kington, 223b, Hammersmith Rd., London, W. [2485

B.S.A., 4¼h.p., 3-speed, special sidecar, hood, screen, etc., brand new, 87 gns.; 1913 B.S.A., 2-speed, clutch, 27 gns.—Rider Troward and Co., 31 and 78, High St., Hampstead. (D) [2455

1917 B.S.A. Model K, large Canoelet sidecar, luggage grid, disc wheel, apron, very large P. and H. lamp, very large twist horn, rear lamp, sidecar lamp, and generator; £60.—Walbro Cycle Co., Saffron Walden. [X0149

1916 B.S.A. Model K, with large Canoelet sidecar with apron, P. and H. lamp, rear lamp, and £1/1 Lucas horn, and £5/5 Smith speedometer, just like a new machine; £55.—Walbro Cycle Co., Saffron Walden. [X0150

BIGGEST Bargain This Week.—B.S.A., 1916, 4¼ h.p. coachbuilt combination, 3 speeds, clutch, K. starter, chain-cum-belt, absolutely as new in every way; £45; call or write quickly.—3, The Mews, Victoria Rd., Clapham, S.W. [2494

4¼h.p. B.S.A., chain-cum-belt, and B.S.A. coachbuilt sidecar, Lucas lamps, Cowey speedometer, mechanical horn, only ridden a few miles, and as new throughout; £75.—Elce and Co., 15-16, Bishopsgate Av., Camomile St., E.C.3. [0552

Campion.

CAMPION, 2-stroke, late 1914, little used; £15.—Brett Bros., Wisbech Fen, Wisbech. [X0155

The Fuel Question.

IT is perhaps dwelling on the obvious to inform our readers that the one supreme interest for all motorists at the present time is any measure that will tend to promise alleviation or amelioration of the fuel situation. The formation of the new Central Council (with which we have already dealt) will have this dealing with the fuel question as one of its main agenda. Our sister journal *The Autocar* in its issue of December 8th, 1917, dealt very ably with one or two aspects of the fuel question as it stands at present under the heading "The First Thing First." *The Autocar* suggested, and undoubtedly rightly so, that the fuel question is the burning question of the day, and must be dealt with and mastered before motorists or motorists' representatives spend their energy and time in other directions. There is, of course, one aspect of the fuel question that is fairly obvious when any thought is given to the question, but it is astonishing how few motorists appear to have realised it, and this is the question of the benzole supply after the war. We all know, or should know, that the output of benzole after the war will be considerably greater than that before the war. On the other hand, it is equally well known that the consumption of motor fuel after the war will be enormously greater than it was before, and that the increased output of benzole will make practically no difference to the situation as far as benzole's meeting the country's fuel demands is concerned. There is, however, one matter in which benzole may perform a very valuable service, and that is in helping, to a certain extent, to keep down the market price of all fuels.

What is expected in many quarters is that after the war certain gas companies will put their superfluous benzole on the market at, say, 1s. 6d. per gallon. If this takes place one of two things is bound to happen; either the whole available supply will be immediately consumed so that the general body of private motorists will receive no benefit (obviously the first supplies will go to commercial users) or, alternatively, the petrol ring will lower the price of their fuel until benzole is driven off the market. When the rival has been finally dispensed with, the petrol companies will once more have a free hand, and will again be able to force up their prices in the way we have so recently experienced. The remedy suggested for these two catastrophes is the formation of a benzole ring, *i.e.*, a kind of ring of gas companies willing to place their benzole on the market after the war. The object of this ring would be two-fold, to prevent benzole from falling under the control of the petrol ring, and to maintain a fixed price of all such benzole as may be turned out.

The launching of benzole on the market on any considerable scale will be an entirely new enterprise, and it is only natural that the gas companies will want some guarantee that the enterprise is likely to be a paying concern, and as far as can be seen at present the only way this can be guaranteed to them is that they should have an assured market and an assured price. Suppose for the sake of argument the gas companies are promised 2s. per gallon for benzole, and not only promised this price but promised a certain consumption per annum. If this consumption is satisfactory the gas companies will jump at the chance of getting rid of their valuable by-product in this way. The step that will be taken by the petrol ring to meet this will most probably be, as we have already suggested, a lowering in the price of their fuel. Now if motorists turn to petrol because it is temporarily cheaper, the aim of the petrol ring will be achieved.

What is most essential is that those who undertake to buy benzole in the quantity and at the price specified must also give an undertaking that they will not be seduced from their agreement by any lowering in the price of petrol. In other words, they must promise not to be led astray by the seductions of the petrol ring.

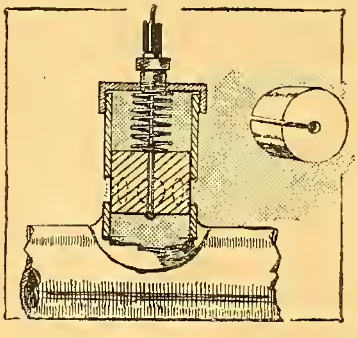
An index to the advertisements in this issue will be found on the page facing the back cover.

IDEAS: Useful and Ingenious.

MAKING AN EXTRA AIR INLET.

IN this time of economy it is possible to build a very efficient and cheap air valve. Take an old brass cycle pump, saw it at about the centre of the screwed cap, make a little round collar to fit the induction pipe. Drill a large hole in the pipe, and three or four little holes in the pump tube. The diameter of the holes cannot be stated, and depends on the carburetter naturally. After the holes are drilled the valve body is soldered on the pipe, this requiring abundant heat on account of the mass of metal.

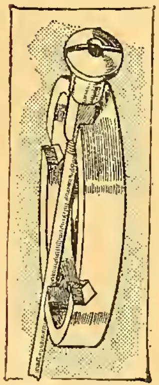
Then take a small piece of round cast aluminium or copper to fit the inside of the tube. With a saw cut it to allow a cable to be inserted in the middle, a spring is added, the cap is screwed, and the throttle is operated by Bowden control or by a screwed rod and wing nut.



An extra air intake made from part of an old cycle pump.

To prevent the throttle turning it is possible to solder a little copper pin in the valve body, which will act as a guide where the throttle has been sawn.

The whole can be plated, and will save many shillings in petrol.—Y.Q., Rouen.



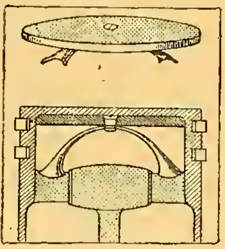
A nipple key made from a worn bracket disc.

MAKING NIPPLE KEYS.

USEFUL nipple keys can be made out of worn bracket discs to suit any size of nipples. The discs, of course, must be heated and softened to allow them to be filed and sawn. The sketch clearly shows how the bracket should be filed to allow the nipples to fit the slots.—Y.Q., Rouen.

INSULATING THE PISTON HEAD.

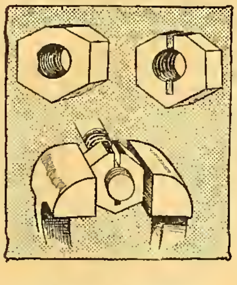
A SIMPLE method of insulating the hot underside of the piston head from oil has occurred to me. It consists in obtaining a circular piece of sheet asbestos, about ⅛in. thick, having its diameter the same as that of the interior of the piston. This is held against the top of the piston by a spring whose crown is fixed to the centre of the disc, and whose extremities rest upon the bosses of the gudgeon pin. The resistance of the spring would hold the asbestos firmly against the piston, effectually preventing oil from coming into contact with it.—DENNIS F. WELCH, Oxford.



An idea for insulating the piston head.

HOLDING A THREADED ROD IN THE VICE.

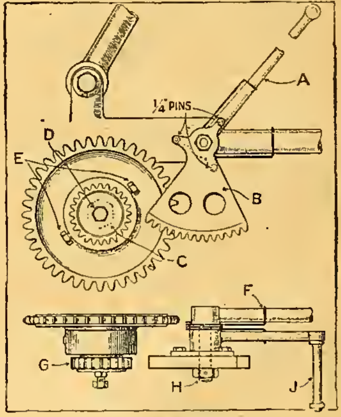
IT is often found to be necessary to hold a rod the end of which is threaded, such as a brake control rod, in a vice. The ordinary lead pads are good enough, but if the rod requires to have any turning pressure exerted upon it, it will be found that the lead will not hold the work sufficiently tightly, and if excessive pressure on the vice is exerted it will be cut through, and the threads on the rod will become eventually damaged. The alternative is to get a nut which fits the rod and file off one corner quite flat. In the centre of the flat make a nick with a file, and then with a hacksaw cut the nut practically in two. The split nut can now be slipped over the threads, and if the jaws of the vice are screwed up it will be found that the work is securely and sufficiently held.—*L'Automobile aux Armées.*



Securing a threaded rod in a vice.

HOME-MADE KICK-STARTER.

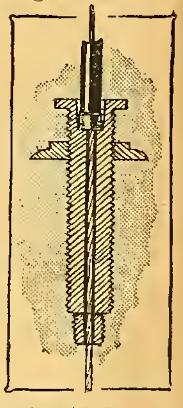
THINKING others may be interested in the home-made kick starter I have devised, which answers admirably, I give the following details. A is a crank, once on a push cycle, with driving wheel removed and pedal J reversed. The crank is secured to the quadrant B by means of three ¼in. pins. A shaft H has taken the place of the original one, which secures the back stays to the frame, but made a little longer to carry the crank and quadrant, which gear with G, which is affixed to the chain sprocket of the two-speed gear. Inside G are three pawls, which act as a free wheel, to enable the quadrant to return to its original position for starting, one kick being sufficient to give the engine two complete revs. A washer C keeps the free wheel on, and also the pawls in position. The ¼in. set pins E prevent the clutch spring inspection cap from unscrewing. A spring F with three coils of ⅛in. wire returns the crank and quadrant to the starting position.—H.G.B., Tibberton.



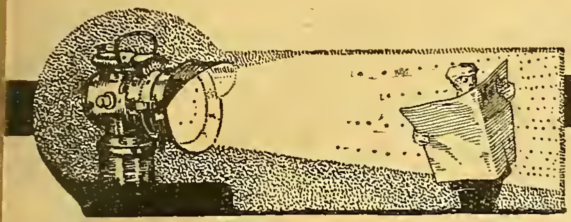
A home-made kick-starter.

IMPROVED BRAKE FITMENT.

VERY often use can be made of an old French cycle tyre valve instead of the ordinary too short thimbles for the brake fittings, the removal of the obturator being the only alteration required.—Y.Q., Rouen.



An old French tyre valve as a brake fitment.



Occasional Comments

By Ixion

A Taste of Old Times.

WHAT little motoring I get nowadays is mostly accomplished in a big car with a slouch-hatted damozel at the helm: but Christmas week brought a delicious reminder of days past, and days soon (I hope) to return. I got out on the moors with my old A.B.C., and a tankful of petrol. The last time I saw G. E. Bradshaw, the A.B.C. designer, he was quite out of conceit with the 1914 model, and if he condescended to talk two-wheelers at all, was full of hints about something quite different and entirely revolutionary. But all I can say is that, if he has something better than the 1914 marque up his sleeve, it will be very, very good. After chugging about on the slow speed, partially sprung, hard service W.D. type of jigger, a few miles of open road on a fully-insulated mile-a-minute mount was a treat to be remembered. The heavy machine began to bark under the merest paddle-off, revved till I trembled for its bearings, ate up hills as if they were not there, and slid over the war-hammered highways as if they were asphalt drives along a sea front. Some bicycle, the double-sprung A.B.C. I had forgotten how extraordinarily good it is: and I ruthlessly turned down three more applications to purchase it at a tempting price.

Experimental Aero Engines.

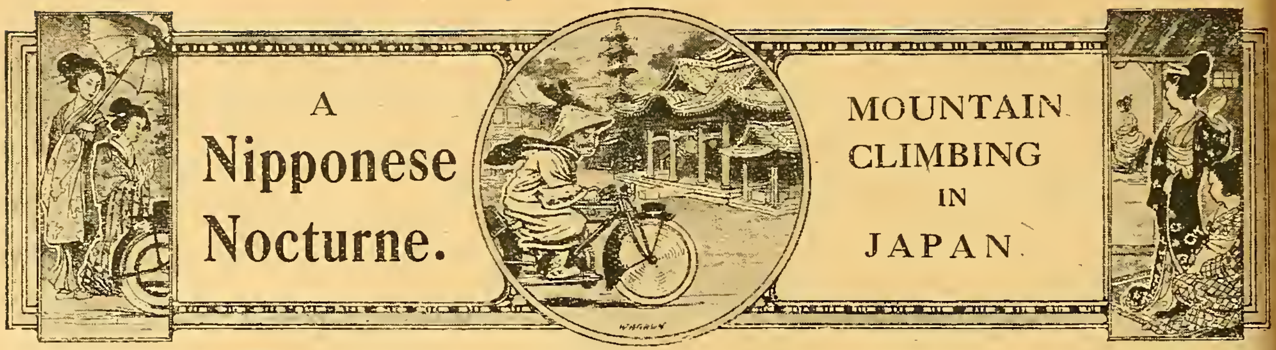
I HAVE not the pleasure of Mr. Philbrow's acquaintance, and in noticing his letter of complaint that the R.F.C. authorities are unsympathetic towards inventors, I am merely treating his grievance as typical of many similar letters to the press, without reference to the merits of any particular case. I personally believe, and many people more qualified to express opinions agree with me, that our own engine experts have erred in the other direction. So far as engines shot down up to date afford a basis for judgment, the German authorities have absolutely barred out every original and unorthodox engine. They have limited themselves since August, 1914, to the conventional products of half a dozen of their best factories, and have concentrated their production almost exclusively on the six-cylinder vertical aero engine. Our own departments, on the other hand, have encouraged a weird variety of designs and designers: in many cases, wholly experimental engines have been financed by the Government. No nation has shown a greater readiness to listen to untried men, and to give untried notions of apparent promise a fair trial. Designs like Mr. Philbrow's, and those of other naturally mortified inventors, who have published similar complaints, enter into competition with other secret designs, and are judged by the best experts in the country. The names of the staff concerned, both as regards production and technics, include many engineers who have "made good" in the industry, and other engineers whose reputation is rather scientific than commercial. An individual engineer, in his pardonable and natural disappointment, is always ignorant of two vital factors. He does not know what rival designs have been given the preference over his: if he could see the drawings accepted at the very session where his own scheme was turned down, he might not agree with the decision, but he would at least admit that the experts had a plausible case. Secondly, he cannot give full value to the question of production. Under the stress of war conditions, it is not a matter of securing the engine which will give the last ounce of efficiency per c.c.: it is more often a question of which design can be produced in hundreds most rapidly and most easily, with the materials and labour at our disposal. I happen to know a little more than Mr. Philbrow does of these matters, through my touch with the trade: and I, personally, have considerable confidence in the designs department of our air organisation. If I wanted to criticise them, I should take the diametrically opposite line: and say that we should be in a stronger aerial position if we had dallied less with the untried inventor, and concentrated more along Hun lines upon quantity production of tried and conventional designs. This, as regards the past. So far as the present and future are concerned, I hope we are very close to the happy mean.

Dangerous Ground?

SIMILARLY, L.-Cpl. Reeve is theoretically on dangerous ground when he asserts, as against Mr. Aston, that the seven-cylinder rotary is necessarily obsolete. Rotary engine design has turned largely on the crux of efficient cooling. The difficulty of obtaining perfect air-cooling with large cylinders certainly caused a wide adoption of nine smaller cylinders as opposed to seven larger cylinders: and so far L.-Cpl. Reeve is right. But from what leading designers have stated and prophesied about air-cooling of late, some going so far as to vouch for its ultimate adoption on most motor cars in the future, these difficulties are not theoretically insoluble. The decision between a seven and nine-cylinder rotary would then depend upon other factors, one of which would unquestionably be ease and cheapness of production. The seven-cylinder, which our correspondent stigmatises as "obsolete," might then knock the nine-cylinder out of the field.

Auto-wheelist to the Rescue.

A CORRESPONDENT asserts that local repairers have failed to diagnose a fault in his B.S.A. Auto-wheel, and as my own experience of this handy little mount is strictly limited, I publish his case, in the hope that some owner of a sister machine may be able to play the Good Samaritan. The machine behaves ideally on generous throttle openings, but occasionally when it is throttled down the engine utters a sharp staccato crack, like a stick breaking, and drags for a moment.



A Nipponese Nocturne.

MOUNTAIN CLIMBING IN JAPAN.

It was just after tiffin, and the Knut was leaning moodily against the Club door-post when Oilrags walked up, digging within the bowl of an evil-smelling pipe of undoubted antiquity.

"What a life!" groaned the Knut.

"Yes," assented Oilrags; "and this pipe is a baby two-stroke for carbon."

"Try paying a decent price for your 'bacca," returned the Knut. "Anyhow, what about a stunt this week-end?"

"I'm game," said Oilrags. "Where to?"

"I've heard you bragging a lot about some fearful pass that you climbed, or rather pushed your old 2½ h.p. 'bus over in the dim, distant days, before I came out to this blues-inducing, benighted island," chaffed the Knut. "Let's have a shot at it, and I'll show you how it should be climbed."

"It is a bit late to start now," said Oilrags, dubiously. "If the road surface is good we may get over before dark, but if it is bad we shall be nicely in the cart."

"I don't care a rap," snorted the Knut. "I'm fed up with mooning about here. A bit of a thin time will give us something to grouse about. I'm desperate."

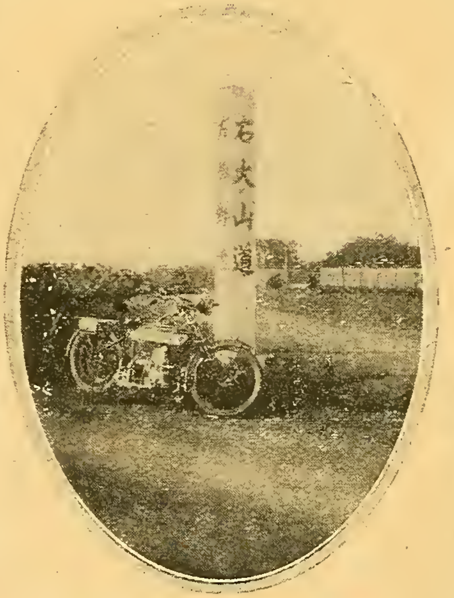
"What's a' this aboot bein' desperate?" enquired the Wee Yin, sauntering up. "Ah'm gey desperate masell'. Bran' noo belt; cost me twal plunks (plunks = slang for one yen, about 2s. 1d.) an' it's cut like the de'il on a wee bit sharp edge o' ma beltguarrd."

"Never mind, Wee Yin," said Oilrags, soothingly. "Only twenty-eight days in this month. Anyhow, would you care to come on a mountain-climbing stunt? Mighty good chance of being stuck in the dark. Shocking bad road, and as steep as the price of spares in Japan?"

"Ah'm jeck easy," replied the Wee Yin, phlegmatically. "Starting now?"

"Yes," replied Oilrags. "Bring some grub, because we shall have to stay overnight on the other side of the pass—if we get over."

"Cheerful blighter," remarked the Knut, as the trio moved off to haul their respective mounts from their sheds. At 2 p.m. the other members of the mess, whilst sleeping off their midday meal, were aroused to violent vituperation by the combined exhausts of a 2¾ h.p. V twin bestridden by the Wee Yin, a 3½ h.p. single (minus silencer) ridden by the Knut, and a 3½ h.p. flat twin driven hard on low gear with malice aforethought by Oilrags.



The author's flat twin Brough beside a quaint-looking Japanese signpost.

The Start—and some Packhorses.

All went well with the trio for awhile. They streaked past the Oyama signpost at a brisk pace, endeavouring to make fast time over the good road to the village of Sekimoto, ten miles distant, where begins the ascent of the Ashigara-toge Pass. When about six miles out, however, the Knut's machine petered out. The Wee Yin was well ahead, but Oilrags, who was in the rear, stopped to assist the Knut. After a few unsuccessful running attempts to get going, the Knut jacked up his mount, and investigated the cause of the stop. A choked jet was diagnosed. It was soon cleared, and the Knut moved noisily off again. Getting towards the hills, packhorses of an excitable nature caused several delays, and Oilrags raised a laugh by unintentionally scaring a wobbling Japanese rider of a pedal cycle into a rice field—an almost dry one, fortunately for the native.

The Wee Yin was overtaken whilst gazing thoughtfully at a trembling packhorse's heels. The horse was standing across the narrow road, and the driver was evidently inviting the Wee Yin to pass between the animal's hind quarters and the road's edge.

"Does the muckle idiot," wrathfully exclaimed the Wee Yin, "expect me to risk ma gude machine anent yon cuddie's heels? Micht as weel hond him ower two months' pay, and ha done wi' it."

After a brief parley the packhorse was led fearfully past the stationary machines, and the motor cyclists continued their journey.

From Sekimoto the climb proper commenced. The grade was easy at first, but the surface was atrocious. Storm water gulleys traversed the road at all angles, and at intervals crude little wooden bridges spanned numerous small streams. Each bridge stood 6in. or so higher than the road at the abutments, consequently crank case bumping was rife. Oilrags, whose machine had a very small ground clearance, had to lift his 280 lb. of iron at almost every bridge.

Nipponese Nocturne.—

After a couple of miles of this work, with a few lditional halts to allow badly scared packhorses to led off the road, the trio of trouble seekers were ell amongst the hills. As the higher levels were ached the grade became steeper and steeper and the irpin bends increasingly acute. The road surface ried from loose sand and gulleys to what the Wee in called "currant bun road," *i.e.*, a surface studded ith projecting boulders.

Many were the involuntary halts, the runs round ose hairpins, and the narrowly verted spills. The Knut's clutch as out of commission, so that lmost every time he stopped his ompanions had to assist him with push off. The Wee Yin's light achine danced like an agonised og over the "currant bun" retches, and Oilrags crept autiously upwards, making much se of his h.b.c. in his endeavours avert the many inevitable colsions between his crank case and e "currants."

Night came on, and the Wee Yin, ho possessed no lamp, and had nce or twice all but gone over the dge of the road, where a long drop nto the valley awaited him, cried Enough." The Knut half greed, for he had put in a lot of trenuous push-starting; but Oilags, who had done quite well in the ay of avoiding crank case colisions for the last mile or so, was or keeping on. He let in his lutch for a fresh start, and had ravelled but a few yards when his ngine raced furiously. Frantic anipulation of clutch and gear levers made no difference. Something had gone, so he altered his mind, nd also cried, "Let's quit." The travellers were ut a quarter of a mile from the summit of the pass 2,500 feet above sea level), but the last few hairpins vere terrifying. Steep, loose, and acute; it was not vise to attempt them in the dark.

The machines were pushed to the side of the road, hich had narrowed down to a width of about 4ft., nd Oilrags then discovered that his belt fastener had roken.

ON THE ASHIGARA-TOGE.

The road surface varied from loose sand and gulleys to what Wee Yin called "currant bun road"—*i.e.*, a surface studded with projecting boulders.

Taking the Knut's lamp, the trio left the motor cycles and started away to walk the six miles over mountain footpaths into Suruga town. It was an eerie walk, for in places the light of the Knut's acetylene lamp, when directed over the cliff's edge, failed to reveal anything but space, and a slight mist tended to obscure the faintly marked foot track.

After an hour or so of walking the lights of Suruga became visible down in the deep valley of the Sagami river, and the travellers were soon installed in an inferior Japanese inn.

Next morning a return was made to the summit of the pass, whence a comprehensive view could be had of the pass winding and twisting away down the mountain side; but the dull weather made photography impossible.

Descending to the spot where the climb had been abandoned on the previous day, the disappointed trio found their motor cycles covered with dew, but untouched; for nobody, except perhaps a few native woodcutters, use this pass as a rule.

Snow was falling and a bitter wind swept the hill tops when Oilrags set to work upon his broken belt fastener and his companions began coaxing their gummy engines into life.

Loud and echoing maledictions from Oilrags upon some person or persons unknown startled the other two blue-fingered motor cyclists. It appeared that the spare belt fastener that Oilrags always carried was missing. Of course, neither the Wee Yin nor the Knut had a spare.

Oilrags started to lace the belt with a spare length of Bowden wire, whilst the heat of his annoyance and subsequent utterances increased in inverse ratio to the temperature of his numbed fingers. However, it was a strong-looking job when it was finished, and the trio began the descent of the pass.

Except for an occasional slide on the muddy patches caused by the melting snow, nothing untoward happened to the thwarted trio as they journeyed homewards; but all three were inwardly resolving to do no more "absurd stunts."

* * *

CARBIDE FOR DOCTORS.

DOCTORS who use motor cycles in their practice in carrying out night journeys have found great difficulty in obtaining calcium carbide owing to its prohibited sale, whilst electric lighting outfits cannot be purchased, and a satisfactory oil lamp for use on a motor cycle is difficult to obtain. Lucky are the few who possess machines fitted with self-contained electric installations, thus rendering them free from all irksome restrictions, for to many the carbide difficulty has proved a very real one of late. This being the case the Auto Cycle Union has offered to investigate and report upon applications from medical practitioners for calcium carbide for lighting the lamps of their motor cycles when on professional journeys at night time.

The Ministry of Munitions has expressed its thanks for this offer, and has announced that such applications for a permit under Paragraph 4 of the Order of 24th September, 1917, will receive consideration within the limits of the supply of carbide available.

Doctors should therefore make application to the secretary, Auto Cycle Union, 83, Pall Mall, S.W.1, for a form on which to apply for a permit to purchase.

MILITARY NOTES

The Oldest Despatch Rider: Another Cyclist's Exploit: Recent Honours.

A MOTOR CYCLIST'S EXPLOIT.

IN the wonderful attack by the Italians on the occasion of their recapture of Mount Asolone, a motor cyclist officer signally distinguished himself. The chief brunt of attack was borne by the Cuneo Brigade and the 240th Regiment of the Line, whose Colonel, when all communications had been destroyed by the enemy's fire, himself worked a heliograph when the light permitted. North-west of Asolone, where the troops held gallantly to their original line on a plateau despite all assaults, a young staff officer went along the line encouraging the men and carrying orders on a motor cycle, which in some extraordinary way he managed to keep upright, bounding over ground where there was no road and dodging between trees, all the time under fire.

* * *

A REAL SKY PILOT.

THE central figure in the accompanying photograph is Lt. R. M. Bankes-Jones, R.F.C., who was in the Church prior to the war. Shortly after hostilities broke out he took up a post, as announced in these pages, as an Army chaplain, and after having served two years Overseas he resigned his chaplain's commission and was recommissioned into the R.F.C. He succeeded in getting his wings five months ago.

Pilots of the R.F.C. Reading from left: Lt. Anderson, Lt. R. M. Bankes-Jones, and Lt. Mooney.

In a letter to us he says: "It would be very interesting to know how many of the fellows who used to compete in the English and Scottish Six Days Trials have since become R.F.C. or R.N.A.S. pilots. I believe motor cycling is a good preparation for air work. The two other parsons who have joined the R.F.C. are B. H. Davies and P. Bischoff, and we all three rode in the 1914 Scottish Trials."

* * *

FOR VALUABLE SERVICES.

IT is with great pleasure that we note that Col. F. Lindsay Lloyd has received the Order of C.M.G. "in recognition of valuable services in connection with the war." Col. Lloyd is, of course, well-known to our readers as having been clerk of the course of the Brooklands Automobile Racing Club and chairman of the British Motor Cycle Racing Club. His work in connection with automobiles and motor cycles as regards the Army during the past fifteen years has merited the fullest recognition on the part of a grateful country.

Among the promotions which have been given to officers for valuable services rendered we note the name of J. Forgan Potts, R.N.A.S., who has been promoted from Flight-lieutenant to Flight-commander. Before the war he was a private owner racing motor cyclist.

* * *

DEATH OF A MOTOR CYCLIST SOLDIER.

WE greatly regret to have to announce the death of Lt. W. Howard, R.G.A., the only son of Mr. and Mrs. Howard, of Walton-on-Thames, who died of wounds shortly before he would have celebrated his fourth Christmas in France. He had been out at the Front since Mons, and before the war was a pupil with Messrs. H. Collier and Sons, Ltd., Plumstead, the manufacturers of the Matchless motor bicycle.

His ambition in life was to be a motor cycle racing man, and prior to the war he was already beginning to shine conspicuously in competitions, notably in the B.M.R.C. meeting of June 19th, 1913, where he finished fourth in the 1,000 c.c. handicap race, riding a 5 h.p. Matchless, and in the kilometre and mile speed trials on September 18th of the same year, in which, on his 5 h.p. Matchless, he covered the kilometre and mile at a speed of 68.44 miles an hour.

RECENT HONOURS.

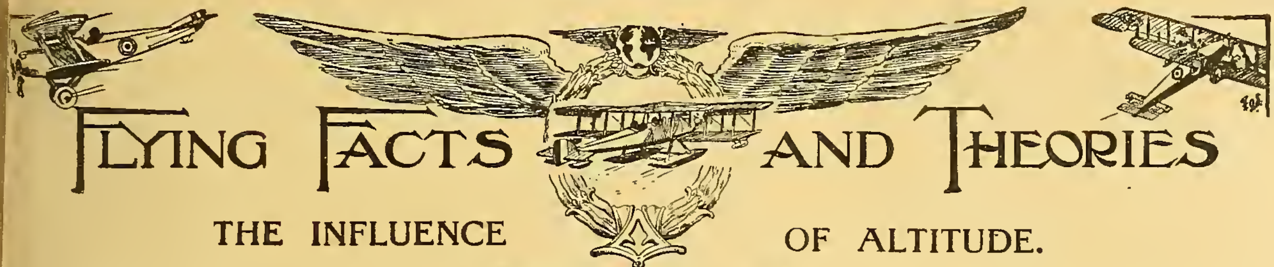
IN the *Gazette* we notice the names of the following well-known motor cyclists mentioned in despatches: Temp. Capt. E. A. Colliver, the rider of an Indian, and a partner in the firm of Godfreys (Great Portland Street, London, W.); Temp. Capt. C. T. Newsome, the well-known Rover exponent; Temp. Sec.-Lt. J. T. Van Hooydonk, an old-time motor cyclist; and Temp. Capt. G. J. W. Gatehouse, who before the war was an enthusiastic motor cyclist.

* * *

THE OLDEST DESPATCH RIDER.

CPL. R. SOMERSET, writing from Mesopotamia, says: "I have seen in recent issues of *The Motor Cycle* a discussion as to who was the youngest despatch rider on foreign service. It caused a good deal of interest among them. Now I should like to ask who is the oldest D.R.? My age is forty-eight years, and I have been on active service three years with the Lahore Division, Signal Company. One year was spent in France and two in Mesopotamia. I enclose my photograph, which was taken in the winter in Mesopotamia."

Cpl. R. Somerset, D.R., whose age is 48 years. He asks, "Who is the oldest despatch rider?"



FLYING FACTS AND THEORIES

THE INFLUENCE OF ALTITUDE.

By W. G. ASTON, A.M.I.A.E.

IN discussing the performance of various aeroplanes, particularly in regard to their climbing abilities, I have recently been rather struck with the fact that most people are lamentably ignorant of the effects which height above the ground has upon the flying capabilities of a machine. Ever since the earliest days the altitude to which aeroplanes have attained has steadily increased, the best effort up to date being somewhat about five miles, or roughly equal to the height of Mount Everest, not neglecting the meticulous two feet which ultra-scholarly geographies are in the habit of adding to its recognised 29,000.

Now, the height to which an aeroplane can climb is not dependent, as many seem to think, upon the breathing capabilities of the pilot: indeed, nowadays no pilot would think of attacking an altitude record without a self-contained oxygen apparatus, and probably some warming contrivance as well; it depends, other things being equal, upon the weight per horsepower of the machine, and, as this is a definite ratio, so there is a definite limit to the height to which it can soar. This is very neatly called the "ceiling" of the aeroplane, and such "ceiling" is an important characteristic, which is to be considered in relation to the machine's maximum and minimum ground speeds and rate of climb generally, in order to arrive at its all-round performance.

Atmospheric Density.

The higher one goes above the surface of the earth the less is the density of the atmosphere owing to the effect of gravity upon its particles, that is to say, the weight of each layer is taken by the layer immediately below it, hence those at the bottom are more compressed than those at the top, where the air is comparatively rarefied. For the purpose of measuring heights on an aeroplane an aneroid barometer is employed. This instrument, however, does not show altitude accurately, since it merely indicates atmospheric density; corrections must therefore be made in order to accommodate the varying factors introduced by temperature, humidity, etc., at ground level; even then the record of the barometer is not perfectly accurate, though it is sufficiently so for all practical purposes.

Varying atmospheric density has several important primary effects upon an aeroplane. First of all, it alters the resistance both of the planes and of the body. (These two, as we shall see later, require separate consideration.) Next, it alters the explosive mixture delivered to the engine, as well as the degree of completeness with which the cylinders are filled. Again, since it affects resistance, it also influences the working of the air screw, and, for the same reason, it makes a difference to the reading of the air-speed indicator. In the case of water-cooled engines it alters the temperature at which the water boils. All these effects are felt not only by aeroplanes, but by other machines. For instance, motor cars when taken to high altitudes not only boil their water much more readily, but give less power, besides requiring adjustments to the carburetter.

In order to get an idea of the combined effect which these influences produce, we will briefly consider the principal ones separately, but it must first be pointed out that this is purely an elementary consideration in which only the more prominent points are discussed; it makes no pretensions to discussing all the conditions concerned.

The Resistance of the Wings.

One cannot deal with the resistance, or drag, of the machine as a whole because it is made up of two parts, that which is produced by the lifting elements, and is consequently subject to variation according to the angle of incidence, and that which is due to the body, framework, tail, engine, etc., and may be regarded as the same throughout the range of angles of incidence which are likely to be employed. The latter is called body-drag and the former wing-drag.

The upward thrust, or lift, which is furnished by the planes of a machine, depends upon the weight of air which they accelerate downwards. If, therefore, both the speed of the machine and the angle of incidence of the wings remain constant, the *volume* of air deflected will also remain constant, and this means that the lift will decrease as the machine gets higher, since the weight or density of air is inversely proportional to the height. To counteract this decrease in lift it is necessary to increase the angle of incidence so that a greater volume of air is dealt with. If the ratio of lift-drag were the same for all angles of incidence it would follow that, provided the same degree of lifting effect were obtained by altering the angle of incidence at various heights, the resistance would also be constant. As a matter of fact, the lift-drag ratio does alter with the angle of the wings, but this alteration is not very big through the range of angle called for, consequently we can look upon the wing resistance as being practically unaffected by height. It is interesting to note, in passing, that although there is a general tendency for the lift-drag ratio to decrease as the angle of incidence is increased, exactly the reverse effect takes place below a certain small angle. Hence it may happen that if an aeroplane is designed so that the wings are at a very small angle when flying level just above the ground, the wing drag can actually get slightly less as the angle of incidence is increased with an increase of altitude, but it will get greater again after a certain point is attained. For

Flying Facts and Theories.—

the purposes of the present article, however, we will neglect this effect and consider that the wing-drag remains constant at all altitudes for a constant speed. This is not quite the truth, but it is not very far away from it.

Body Resistance.

The drag of the machine other than that of the wings can be regarded as, roughly, independent of the angle of incidence, provided the altitude is unchanged. Such drag is, however, dependent upon, and directly proportional to, the density of the medium through which the machine moves. As this density gets less with increasing height it follows that the body drag will also get less as greater and greater altitudes are attained.

Total Resistance of the Aeroplane.

Since one part of the aeroplane's resistance is unaffected by height and the other decreases with increasing height, it follows that the total resistance takes a mean between the two, and also decreases with increasing height, though not to the same extent as does the body-drag. Given a constant thrust, therefore, the higher a machine goes the faster it will fly. In other words, for a constant speed it will have less resistance.

It is important to note that the necessity for increasing the wing angle with increase of height is subject to the aeroplane speed remaining constant. The required constant lift can be furnished by meeting the decrease of air density by an increase in speed. If the power of the engine were not affected by height, but remained at all altitudes the same as on the ground, then the angle of incidence would be also kept the same, and the speed would be increased in inverse proportion to the density.

Engine Power.

Unfortunately, petrol engines of the present accepted type do not give the same power at different heights, but their output falls off as more and more altitude is attained. The power a petrol engine gives is dependent upon the weight of fuel which can be completely burnt in the air contained in the cylinder. If the density of the air falls off, then the weight of fuel introduced must also be diminished. If not, and the supply of fuel is kept the same as at ground level, then as the altitude is increased the mixture will grow more and more rich. To counteract this a hand controlled mechanism is generally incorporated in the carburetter by which the strength of the mixture can be regulated in accordance with requirements.

This alteration of mixture strength is, therefore, a matter of small importance compared with the fact that the explosive charge in the cylinder will decrease in weight as the altitude is increased. Consequently the power will fall off, and it will do so, provided its revolutions are unchanged, at a rate approximately proportional to the density of the air. Taking the normal density of air at ground level at 100, the following scale gives roughly the density at various heights:

1,000ft.	96.4	10,000ft.	69.0
2,000ft.	92.5	15,000ft.	57.4
5,000ft.	83.0	20,000ft.	47.8
8,000ft.	74 5		

On the basis of these figures, an engine at 20,000 feet will only give at constant r.p.m. about half its power at ground level.

Leaving aside for the moment the question of air-screw efficiency, we have, then, the following conditions. The resistance of the aeroplane falls off less rapidly than the density, whilst the power of the engine, which, of course, should be directly proportional to the resistance, falls off more quickly than the resistance. As a result, it is unavoidable that as it increases in height the aeroplane should go slower, as it is only by this means that it can fly with less power.

The Ceiling.

It is clear, therefore, that at a certain point the two factors will become equal, and then no further altitude can be attained. It is this point which is called the "ceiling" of the machine, and it is hastened by the fact that beyond a certain point an increase in angle of incidence will impose a disproportionate drag.

One cannot, however, simply plot curves for these two factors and take their meeting point as the "ceiling," as certain secondary matters have to be taken into consideration.

When the aeroplane goes slower the engine will also go slower (as explained in a previous article). Hence its power will suffer a decrease in addition to that imposed by the reduced air density. Since as a general rule engine power is proportional to revolutions, we may take engine power, in this case, to tend to be proportional to aeroplane speed. This reduction in power, of course, will cause the aeroplane to travel more slowly, unless its effect can be neutralised by having a change-speed gear or variable pitch air-screw, by means of which the engine revolutions can be kept up.

Another result of reduced aeroplane speed is a decrease in air-screw efficiency, by reason of the angle of attack of the blades growing larger; thus there is still another agency working against the speed of the machine. Hence the "ceiling" will occur at a lower height than might seem to be dictated by first considerations.

Variable Pitch Air-screw.

There are two obvious ways of overcoming, or at any rate lessening, these difficulties. One is to use an engine of ordinary type of such excessive power at ground level that, in spite of the calls made upon it, there is still ample at great heights. This has the disadvantage that at low altitudes the engine if fully opened out might rack itself to pieces, as it would then overpower the screw, though this objection could be met by controlling the throttle with a baro-stat, which would automatically limit the throttle opening at all heights. The other method is to use an engine of a type in which the power output does *not* fall off in proportion to the density, and it is in this respect, needless to say, that the greatest development is to be looked for. A variable pitch air-screw would also be valuable in connection with such an engine.

If constant power for a given number of revolutions but irrespective of height is available, then the aeroplane resistance will decrease, since the same angle of incidence can be employed. In this case the speed will have to be increased, and with it the revolutions

Flying Facts and Theories.—

of the engine. Since resistance is proportional to the square of the aeroplane speed multiplied by the density, it is obvious that in these conditions the speed of the aeroplane at various heights will be inversely proportional to the square root of the density. Thus, referring to the table given above, the speed at 15,000 feet will be roughly 25% more than at ground level, and the revolutions of the engine will also be 25% higher. This in turn means that the power of the engine will increase by an equal fraction. If the revolutions are kept to a constant figure the aeroplane speed at 15,000 will be about 12% higher than at ground level.

Air Screw.—If the speed of the aeroplane is kept constant and the engine revolutions also, then the efficiency of the air screw will remain exactly as it is on the ground, since this efficiency depends—as will be shown in a subsequent article—upon its advance per revolution.

Air Speed Indicator.—This instrument employs the principle of atmospheric pressure, and as this depends upon the density multiplied by the square of the speed, the reading of the dial will be proportional to the square root of the density. At 15,000 feet it will read 75 m.p.h., whereas the real speed of the machine will be 100 m.p.h.

The Need for High Flying.

The question will most likely be asked, "Why should we want to fly at all at such great heights, when much smaller altitudes are sufficient for getting from place to place?" The answer is that for war purposes the ability to get to a great height quickly is of very great importance, whereas in peace times the upper air will be sought on account of its comparative steadiness both in flow and direction, and its freedom from gusts. "The trade winds" of which the aeroplane of the future will take advantage are at a very great altitude.

NAPHTHALENE AS A MOTOR FUEL.

A New Departure involving the Use of a Solid Fuel.

THE fuel question is ever with us, and we are of opinion that it is one that cannot be dealt with too fully or too often. Every discussion, even if in itself not likely to bear fruit, is always pregnant with possibilities, and may lead to something of almost revolutionary importance. One of the latest steps in this direction is the suggestion of using a solid fuel in motor cars, and if it can be used in cars there is no doubt that it can with a little adaptation be applied to motor cycles. The fuel in question is naphthalene, which has long been on the market as a dope for petrol under various weird and wonderful names. The various dopes that have been put on the market have ultimately all been proved to be of little real value, but no one has ever doubted the fuel value of naphthalene itself if applied in a proper manner. It is one thing to use a substance directly as a fuel and another to use it as a dope for another fuel; just as while coal is an excellent heater for a boiler, no one would dream of putting coal into a paraffin burner intended to heat a boiler. Naphthalene is never likely to replace petrol or even coal gas, because the output is relatively limited, and if extensively used as fuel the price will rise. At the present time its price is equivalent to petrol at between 6d. and 7d. per gallon.

Briefly, the system of using naphthalene is to fit to the engine a kind of box, or, if you like to call it so, a carburetter, filled with solid naphthalene, which substance is heated and melted by the engine. Once melted the fuel is maintained in a liquid state by the continuous application of exhaust heat, and is vaporised after the ordinary principles of the old surface petrol carburetter. Of course, there are considerable difficulties in the way of maintaining an efficient temperature, the circumstances being very similar to those obtaining in the use of paraffin, but the difficulties are considerably magnified because the solid naphthalene obviously requires a far higher temperature to convert it into a perfect gas than does liquid paraffin; a temperature of something in the neighbourhood of 500° F. being suggested as most suitable.

Another suggested use of naphthalene is as a carburating agent for coal gas. Some of our readers will doubtless remember the old Albo-carbon gas system, in which an ordinary gas flame was enriched in its light-giving properties by the fitting of a bulb half filled with naphthalene that was heated by the flame, and when heated carburated the coal gas, so increasing the light given without increasing the consumption of gas. As far as we are aware the use of this solid fuel on a motor car is at present in a purely experimental stage, and it is doubtful whether it will ever alleviate the fuel shortage which exists, and which is likely to exist for some time.

THROUGH RUSSIA, TURKEY AND ROUMANIA

The author held up by a camel transport in Armenia.

Incidents of a Great Ride through the Caucasian Mountains into Asia by an Old Competition Rider—Lt. W. H. Bedford, R.N.V.R.

ALTHOUGH for the last two years my chief duties have been that of Technical Repairs Officer with the British Armoured Car Squadrons, which you know have done such magnificent work in Russia, Armenia, Turkey, Roumania, and Galicia, I have always taken a keen interest in motor cycling during all the above campaigns.

Many readers of *The Motor Cycle* will remember me as a keen competitor in open trials on Hazlewood and Rex-Jap motor cycles. Those days were indeed happy, but my ride over the Caucasian Mountains, through Armenia into Turkey in Asia, proved one of the most strenuous rides it has ever been my lot to undertake, but I am sure many would have welcomed the experience. I think I can claim to be the first British motor cyclist to undertake the journey.

I chose my mount very carefully, and as I anticipated extremely bad roads, dangerous bends, and hair-raising mountains to ascend and descend, a light machine appealed to me, so I decided on a 2¾ h.p. Douglas, to which I fitted a two-gallon petrol tank, as fresh supplies were impossible for hundreds of miles.

Starting the journey at five in the morning, I made good progress over that wonderful Georgian road. On arriving at Mount Kasbeck the dust made it very difficult to steer a straight course, but my machine was light, and I am fairly long-legged, so I prevented many a spill by using my feet. Some miles further on I reached the mountains of Passanor, where progress was slow owing to numbers of slow-moving oxen transport bound for the Erzerum Front. At times it was difficult to pass these vehicles, the roads being narrow with-

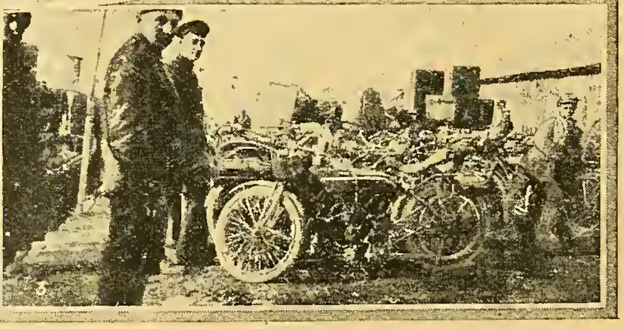
(2) A general view of the mountain roads which wind across the pass.



(3) British and Russian motor cyclists ready to embark.

Through Russia, Turkey, and Roumania.—

out any parapet at the side, and being cut round the mountain side. To misjudge one's distance by a few feet would result in fatal disaster, as one would roll down a precipice of many hundreds of feet in some cases. At mid-day I thought of the sandwiches in my pocket; but alas! they were hard and uneatable owing to the excessive heat, so I had to go hungry—but only for a short time. Later watersplashes were troublesome, but proved a refreshing bath. The Georgian road was good (for Russia), and at last the end came on arriving at Tiflis. Then followed another 250 miles through Besarabia and Armenia in Turkey in Asia.

Twenty-nine Hairpin Bends on One Hill.

For scores of miles there were no roads at all, and the roads that were made were too bad for me to try and describe—my description at the time was "climbing stairs with motor cycles," and a very true one too. Some hills had many hairpin bends, some were particularly dangerous, and one hill, or rather mountain, had twenty-nine hairpin bends; all these could be taken quite well with my Douglas (although later it proved that even our Rolls-Royce cars had to reverse to navigate them successfully), but a good speed had to be maintained, for once stopped on a mountain pass it was impossible to restart, even with such a light machine. The dust at times was up to my flywheel, and brought the machine to a complete standstill. The whole ride proved exceedingly interesting, as the road conditions were quite new to me, also the country—which I can best describe as just "Biblical." The different races of people, who were practically uncivilised, would only stare with wide-open mouths at my motor cycle.

Broken Frames.

Later many of our despatch riders rode over the same course: how rude were my remarks when I counted the number of broken frames that came into my workshop for repairs—not due to bad riding or faulty workmanship, but just to "impossible" roads, which made one think so much of England with its glorious motor ways. For a whole day it was not possible to travel over fifteen miles per hour, and many sore limbs were observed. Commandments as well as machines were broken; but we did the journey for a good cause, and not a sound or grumble was heard when our first shots were fired at the enemy on this Front.

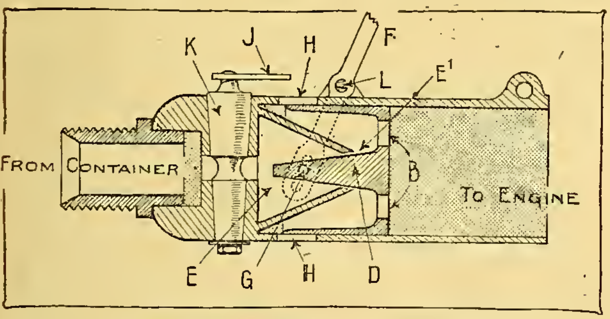
The journey was done in August, 1916, and since then I have encountered many interesting experiences on other fronts.

A COAL GAS CARBURETTER.

The P.S.C. Carburetter, from which the Inventor has obtained Excellent Results.

We have now reached that stage in the use of coal gas for motor traction purposes where we may turn our attention to the consideration of improvements in method. Up till now we have been so concerned with any methods of using the new fuel that we have had little time to consider the best way of achieving this end, and it marks an important step in progress when our deliberations are enabled to take this new turn.

The first endeavour is to obtain improved results from our present type of engines. The chief aim is to guard against waste of gas; the second the method of supply. I have designed a carburetter which would cost very little to manufacture, and could be used with compressed or atmospheric pressure gas. The sketch will give an idea of the principle. The throttle valve has a tapered needle D fitted to the centre B, the ports in the throttle valve, through which the gas passes to engine. G is a pin screwed into the throttle valve, which works in the slot on the control lever F, which rocks on pin L. When the control lever L is brought back it takes the throttle valve forward, opening the air ports H, at the same time opening the gas ports E at point E1 (the air ports H should be relative to the opening of gas ports E1). The air ports, being behind the gas port, give better results, and would curtail the waste of gas. When the throttle is closed it shuts off the supply of gas. We come now to the advantage of the supply cock K with the operating lever J. The gas port E must be large enough for the supply of gas at atmospheric pressure. Should compressed gas be used, the flow of gas can be controlled by regulating the supply through the supply cock K. One must take into account if compressed cylinders are used that the pressure of gas decreases as the gas is used. The supply cock is for that purpose, and can be regulated according to the reading of the gauge. Practically an even supply down to atmospheric pressure could be obtained; the positions would be found by experiment. The throttle could be operated by Bowden control (this would dispense with lever F) and a small lug cast on the side of the body with adjusting screw-fitted nipple on the end of the wire with a hole in to fit on the pin G. A spring could be used in various positions in connection with this method.



Carburetter designed for use with coal gas.

If we are going to have facilities for the supply of coal gas after the war, in compressed cylinders (and there is no reason why we should not), it would do no harm to turn our attention to a double purpose carburetter which could be used either for petrol or coal gas.

G. R. Player, A.M.I.A.E.

WIRING AN ACCUMULATOR LIGHTING SET.

A Selection of Letters from Readers setting forth Various Solutions to the Wiring Problem advanced by "Chinook."

To the Editor of "The Motor Cycle."

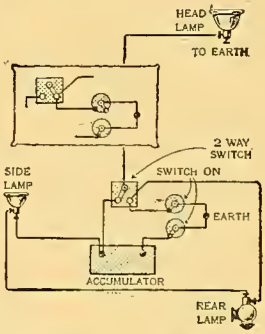
Sir,—My thanks are due to your many readers who have been so good as to write you or me personally *re* the problem of wiring three lamps, two of which are "earthed" to the frame (the third, the sidecar lamp, being mounted on the sidecar body, and therefore insulated) in such a way that all three can be thrown into series, thus consuming a minimum of current from the accumulator when the machine is left standing at the roadside. Such a generous response is really refreshing, and the variety of schemes set forward, each differing from the rest widely or in some detail, is a good illustration of the convenient adaptability of electricity as a lighting medium.

CHINOOK.

[We append, in an abridged form, a selection of the ideas received, and regret that, owing to restricted space, we have had to withhold a large number of interesting suggestions.—Ed.]

Mr. F. Reynolds: "I venture to send a sketch showing one way of doing what 'Chinook' desires, which may be of some use to him and others.

"It will be necessary to insulate the tail lamp from the machine as well as the side lamp, but this can easily be done with the aid of a little insulating material, such as red fibre inserted between the clips holding the lamp bracket to the frame of the machine. A two-way switch will also be required in addition to an extra tumbler switch of the usual pattern.

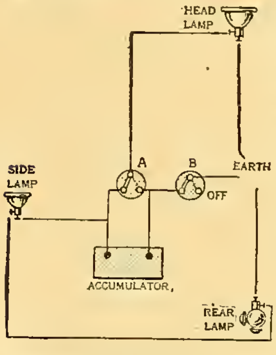


"The diagram gives the position of the switches when the side lamp and tail lamp are in series, and the head lamp in direct circuit with the accumulator. The inset shows the position of the switches for all three lamps in series.

"It will be seen that whichever system is in use at the time the original switch as fitted to 'Chinook's' machine will control all the lights, and no 'short' can take place by wrongly manipulating the switches."

Mr. A. Watson: "In answer to 'Chinook's' request for a method of connecting up his three lamps in series at will, this can be done in a few minutes by the addition of a two-way switch without any extra wire, or at most only a few inches.

"Call the full line position of each switch 1 and the dotted line position No. 2, then we get with: A1 B1=full lights (side and tail in series). A1 B2=no lights. A2 B2=dim lights (all in series). A2 B1=side and tail lights only.

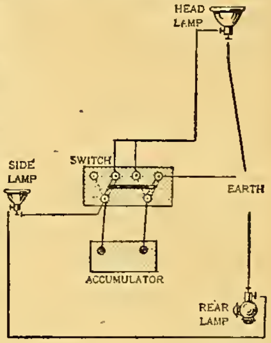


"The operation of the switches would be simplified if they were coupled together. Then, if they were wired correctly, we should get only positions 1 and 3. Position 4 is not required, and position 2 can be obtained by switching off the head light, or any of the three lamps by its own lampholder switch.

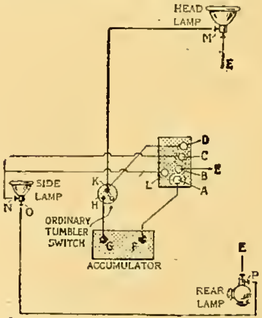
"This may seem rather complicated on paper, but in reality it is very simple. Suppose you are riding with lights out and wish to light up. First switch on the head lamp by its own switch, when all three lamps will light in series. Then switch over the two coupled switches, and the lamps will be put in parallel.

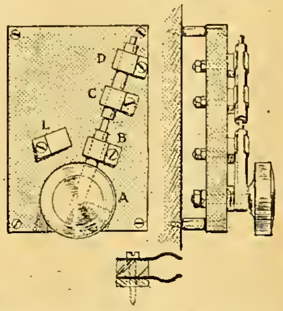
"It would be as well to put the side and tail lamp switches out of action, otherwise, if the lights were put out by either of these, it would necessitate stopping, or reaching over to them to light up while running."

Mr. J. Grundy: "I was very much interested in 'Chinook's' article on accumulator lighting sets in your issue of December 27th. I notice he requires a system, which will permit all three lamps being thrown in series if desired, for leaving the machine standing, and I have pleasure in enclosing a wiring diagram which fulfils this requirement. The switch at present in use would be replaced by a two-way change-over switch provided with an 'off' position; this could be purchased for a shilling or two, or could be made at home. There would be very little extra wire required, and the existing connections to all three lamps would not be disturbed. Two separate switches could be employed if desired, as suggested by 'Chinook,' but if the rider forgot to leave one in the 'off' position before switching in the other, a short circuit would be caused and injury to the accumulator would probably result."



Mr. W. E. Cottis: "In 'Chinook's' interesting article on accumulator lighting in *The Motor Cycle* for December 27th, 1917, I notice at the end he hankers after a system of wiring whereby he can switch all his lamps in series when standing the machine at the roadside. I give below a diagram, the wiring of which achieves this by the addition of a simple two-way switch, which can be made at home by anyone who is used to pottering about with a few tools. I also give rough sketches of how this switch can be made.

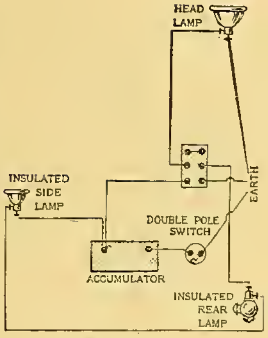


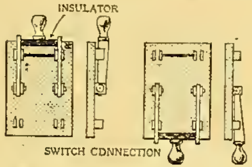


"The arm of the switch is made of hard wood or fibre rod with two brass sleeves over it so that when turned to the right it has the effect of shorting A to B and C to D separately. The current would then flow from the accumulator terminal F to A and through B to earth. Then from the other terminal G to H, through the tumbler switch to K, thence to M, through the head lamp, and back to earth. This gives full light at the head. Starting again at G, through H and K to D, through the twist switch to C, from there to N, through the side lamp to O, thence to P, through the tail lamp to earth, returning to the accumu-

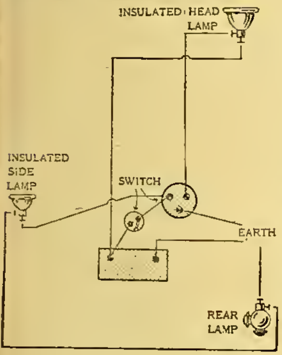
Wiring an Accumulator Lighting Set.—

ator through B and A and F, gives us the side and tail lamps in series. Now, by turning the twist switch to the left we get the current flowing from F to A through the switch to L, thence to N through the side lamp to O and P, then through tail lamp to earth. From here to the head lamp earth, through the head lamp, thence to M and K, returning through the tumbler switch to G. This gives us the whole three lamps in series. The tumbler switch is used for shutting off all lamps in either wiring."





MR. S. BARNETT: "'Chinook' is on a wild goose chase unless he is willing to make a certain amount of alteration to the principles in his system. I was once up against a similar difficulty, and as I often had to leave my machine standing its solution was a rather urgent matter. The accompanying diagram should make my method clear."

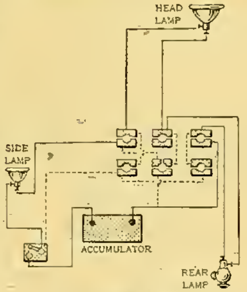


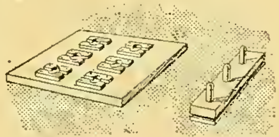
MR. E. WHALLEY: "'Chinook's' small difficulty can be overcome by utilising an extra two-way switch and altering the existing switch to the battery side instead of the earth; also the head lamp will have to be insulated as well as the side lamp. The only difficulty is that the head lamp will have to be operated by its own switch."

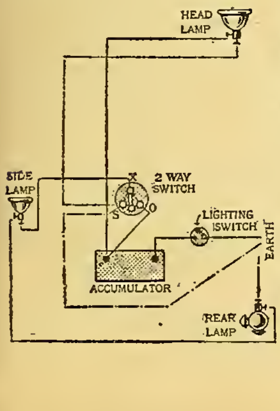
MR. C. A. COPINGER: "I have pleasure in submitting a simple means of accomplishing 'Chinook's' desired result, the only requirements being two three-way plugs, which he could make himself or obtain from any electrical stores.

"He, of course, would have to insulate the lamp fittings from the cycle frame, and this would be in any event a great improvement, as by using the frame as a conductor a much greater strain is imposed on the battery than occurs when using two good copper wires.

"In my sketch, by putting the plug top in the upper plug connects all lamps in series, and in the lower plug in parallel."







"SPARKS": "In view of the fact that 'Chinook' has three earth points, it is impossible to obtain the results that he desires, but by employing another switch and detaching a wire when the machine is at rest the following might suit:

"Two-way switch at O for running—*i.e.*, head lamp to E, side and tail in series to E.

"Two-way switch at S for stationary—*i.e.*, all lamps in series, but E to be disconnected at head lamp.

"Dotted line shows extra wiring required."

"C.E.S." says: "I should like to bring forward a system by which, as 'Chinook' suggests, all the lights may be left in series whilst the machine is standing.

"By adapting a Marvel change-over switch (A. P. Lundberg and Sons, Liverpool Rd., N.), and connecting it as shown, the desired result may be obtained.

"As will be seen, the Marvel change-over switch has six terminals, which are connected by the rocking contacts, as shown in fig. 2 (*b* and *c*).

"The connection shown in fig. 2 (*a*) is to be made by the person fitting switch. The No. 2 terminal is not to be connected in any way.

"The single pole switch is simply used for cutting the current off, the Marvel switch having no 'off' position."

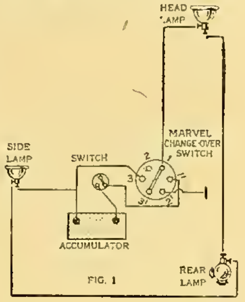


FIG. 1

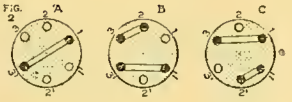

FIG. 2

AIR-COOLING FOR CARS.

ALTHOUGH motor cyclists, as such, are not necessarily interested in the engine arrangements of motor cars, an article by "Runabout" in our sister journal, *The Autocar*, of December 29th, should prove of general interest. The question of air-cooling for cars is the subject he takes, and from his own experiences he contends that this type of cooling for cars can be quite satisfactory.

Quoting a leading car designer, he says that no petrol engine can develop its full efficiency at the temperature of the boiling point of water. This implies, of course, that no water-cooled engine can ever be thoroughly efficient, because the cooling arrangements will break down before the engine really gets to work. The result of this discovery in the case of this particular designer has been the final scrapping of water-cooling, irrespective of horse-power and size of cylinders.

A Successful Air-cooled Car.

Most of our readers will be aware of the existence of the Franklin car—an air-cooled car that has for many years been on the American market, and has given every satisfaction under the most arduous tests and in the most regular service. "Runabout" dwells on an oft-treated topic when he says that experiences gained before the war are now so antiquated that they cannot be soundly applied as precedents in the judgment of such a question as this, and he says the dogma of the designer already mentioned is that with a proper cooling system and a suitably-designed cylinder it actually pays to run an engine at far greater temperatures than were previously regarded as allowable. Needless to say, there are still considerable obstacles to be overcome before air-cooling for cars can become a regularly accepted thing, and the two obstacles that give "Runabout" the most trouble are sparking plugs and the appearance of the complete car.

Personally, we are inclined to think that the sparking plug question can be easily overcome, and we agree that the appearance of a car is really judged only by what one is used to. When a novel design has become firmly established and is a common sight on our roads, it automatically becomes a standard of judging beauty in itself.

As "Runabout" says, custom is everything in these matters. In the early days of the motor car we missed the horse and reins; similarly the blunt and businesslike snout of a Clerget-engined scout aeroplane is not now regarded as anything very heterodox, but only different from the commoner type of plane.

The use of aluminium in cylinder and piston construction also has an important bearing on the topic of the air-cooled car, and, as all motor cyclists know, it is likely to be of great importance in the future development of the motor cycle. There is also little doubt that development of the air-cooled car will materially assist development of the motor cycle, as the two types, now so different, will tend to run, in engine matters at least, on convergent lines

THE LATEST PETROL AND GAS ORDER.

A Summary of the Motor Spirit (Consolidation) and Gas Restriction Order.

THE new Order, relating to which a preliminary announcement was made some days ago, has now been issued by the Board of Trade consolidating and amending the present Motor Spirit Restriction Orders and controlling the use of gas for driving motor vehicles.

So far as private motor cars and motor cycles are concerned no substantial change is made as to their use, but advantage has been taken of the experience gained from two months' working of the present Order to clear up points upon which some doubt was found to exist. The chief points are as follow:

"Necessary household affairs" means the obtaining and carrying of food, fuel, stores, medical and surgical requisites, visits to a registered medical practitioner, dental surgeon, legal adviser, professional agent, or banks, the conveyance of children or young persons to or from a school.

"Performance of a public duty" includes attendance at or upon any court of justice, or at or upon anybody or person exercising public duties, when such attendance is in connection with the business of such court, and the performance of their duties by officers of police and fire brigade, but for the purposes of this Order does not include attendance at a place of worship.

"Red Cross work" means (*a*) the conveyance of sick or wounded persons of His Majesty's Forces for hospital or medical treatment; (*b*) the conveyance of stores, nurses, and duly authorised officials to and from a hospital in connection with the service of the hospital where the journey cannot otherwise be reasonably and conveniently accomplished; (*c*) the conveyance of a member of a county or district committee of a hospital or of one of the societies hereinafter mentioned to a committee meeting where the journey cannot otherwise be reasonably and conveniently accomplished.

The Order also goes on to allow motor cyclists to take out wounded members of His Majesty's Forces who are otherwise unable to take exercise from and to hospitals for a total running distance not exceeding twelve miles when the journey is undertaken solely for that purpose, or to take them to and from places where they can rest or walk about if the medical officer certifies that such rides are necessary.

It is also pointed out that private motor vehicles may be used for station work in connection with a journey by rail or sea, and generally enlarges upon the items in the Orders which have previously been published.

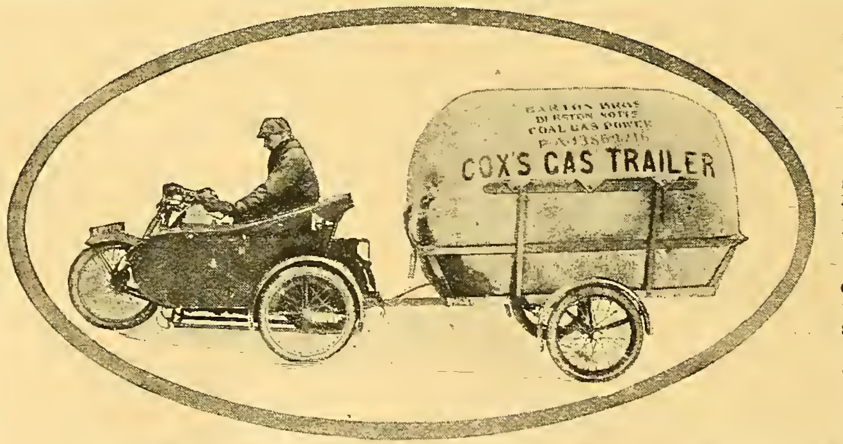
It is interesting to note that it is specifically stated that special permits may be issued for the use of petrol, petrol substitute, or gas for any purpose by any person to whom a special permit in writing has been granted by the Petrol Control Department, and that nothing in the Order shall prevent the use of petrol or petrol substitute obtained on a motor spirit licence, or of gas by the holder of a gas permit, for the purpose of driving a motor vehicle for a distance not exceeding twenty miles in connection with the sale or intended sale of such vehicle, provided that the seller has obtained the permission of the local superintendent or other chief officer of police.

Where at the date of this Order a motor vehicle or motor boat has been fitted with a gas outfit, it may be driven for purposes authorised by this Order without a gas permit until February 9th, 1918. A permit must then be obtained.

* * *

COAL GAS IN PRACTICE.

A Continuation of our Notes founded on the Daily Use of Coal Gas.



IT is an acknowledged fact that improved results are obtained with coal gas if the charge be heated ere it gains the engine, and in running on gas a distinct improvement is noticeable after the induction pipe, etc., has become thoroughly warmed up. In starting it is necessary to turn the gas pretty well full on, otherwise popping back, owing to too weak a mixture, occurs, but immediately the engine is heated up the gas supply can be turned off to the merest sniff.

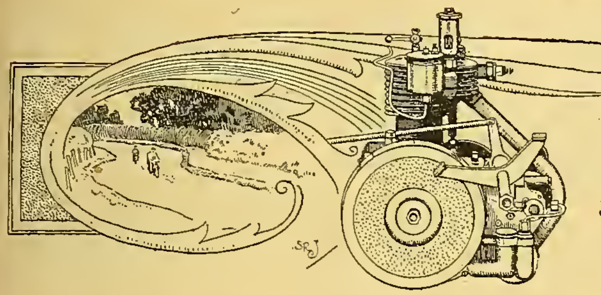
Recently we experimented with a new fitment which permitted the induction of a considerably increased volume of air, it being thought that the air intake used hitherto was somewhat restricting the charge. The fitment was first tried on a comparatively mild evening, and gave perfectly satisfactory results. A keen frost occurred during the night, and next morning, the air being contracted by the cold, a much larger proportion was drawn into the cylinder, and the engine simply would not run at all, owing to too weak a mixture, till we had partially jammed up the air intake by means of a wedge-shaped wooden plug.

Recently, when discussing the matter of coal gas with a Ford van driver who is running his vehicle on this substitute, we came to the conclusion that we were obtaining comparatively good results. This driver, together with several others with whom we have talked, said that he was just able to do his round and nothing more, and that low gear work was constant.

Many of these van drivers complain of overheating, which shows that they are using too rich a mixture. An engine will run on an over-rich mixture of coal gas almost as well as on a correct mixture, the only difference being the ultimate boiling of the water in the radiator, or, in the case of an air-cooled engine, a sparking plug or exhaust valve becoming red-hot. In the case of a water-cooled engine much nicety of adjustment is necessary. The engine is started up on a fairly rich mixture, and the tap then turned off till misfiring begins. Just short of this point is considered correct, but by the time the engine is heated up this mixture is very much too rich, and better results would be obtained if the supply were turned off still further—to a point, indeed, at which the engine would not run when cold. The ordinary gas tap is not sufficiently sensitive to enable the best results to be obtained.

The volumetric efficiency of an engine when using coal gas is essentially lower than when petrol is the fuel used. Whatever pains be taken to vaporise the petrol charge thoroughly, a certain amount of liquid fuel, probably in the form of a wet spray, inevitably gains the cylinder, where it is vaporised by the heat of the piston and the cylinder walls, increasing in volume something about 200 times during the process of conversion. This, of course, does not occur when a dry gas is used, and the only possible method of obtaining a similar result would be to induce pure air and inject the coal gas in a highly-compressed form at the top of the compression and during the firing strokes.

We do not hold up the imperfect vaporisation of petrol as a point in favour of its use as a fuel, but merely mention it as one reason why a higher compression ratio is advisable with coal gas.



ACCESSIBILITY.

SOME CANDID NOTES ON DESIGN, NUTS, AND OVERSEAS TRADE.

By "IXION."

I HAVE just spent a very lurid week in taking to pieces two machines which had been grossly neglected under pressure of war work, and I am now thinking of setting up in business as an accessibility expert. I shall take an office in Portland Street, get hold of the current model of each leading make, take it to pieces, note its defects in respect of accessibility, consider how they can be eliminated either by inexpensive or costless alterations in design, or by the provision of a special tool. I shall then approach the guilty firm, and get well and truly kicked downstairs for my pains. The callousness with which some makers handle this most important subject is really amazing. They are too often content if their own assembling mechanics, armed with special kits, can get the 'bus apart, or together, in a reasonable time; but they have not sufficient imagination to picture the struggles of a private purchaser, possibly resident 300 miles [or 3,000 miles?—OVERSEAS EDITOR] from the works, and ten miles [100 miles?—OVERSEAS EDITOR] from a decent repair shop. Here are actual instances of the fat-headed sort of detail which gets embodied in first-class machines. On a certain machine the front chain can only be adjusted by sliding the engine; the details are fairly well thought out, except that the exhaust pipe fouls the gear box as soon as the engine is moved forwards. The designer has obviously devoted a great deal of thought to his exhaust pipe, which is literally the best designed on the road; but, as soon as the front chain gets slack, you must either buy a new chain or spoil the streamline exhaust pipe by dinting it with a coal hammer.

3D.

THE PRICE OF THE MOTOR CYCLE

TO BE RAISED TO 3D. ON FEB. 7th.

This further increase is necessary owing to the drastic restriction imposed on the import of paper and paper making materials during 1918 and the consequent heavy advance in the cost of paper, but the price will be reduced as soon as circumstances permit.

The subscription rates will be correspondingly raised on renewal or to new subscribers:

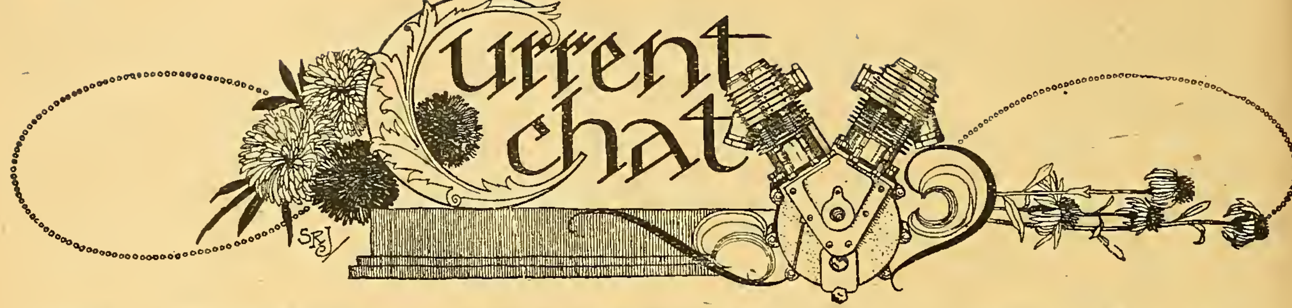
British Isles	15/2 per annum, post free.
All countries abroad..	19/6 „ „

All subscriptions current at the time of reducing the price will be proportionately lengthened for the benefit of each subscriber.

Another Example.

A gear box had to be taken apart because a ball race had begun to rotate in its aluminium bed. The makers might say such jobs ought to be returned to their works, but Overseas owners cannot adopt this method, and no user resident in the more remote corners of England wants to lose his machine for a week or so, for a simple little job that any decent mechanic ought to be able to do in an hour. It took three men four hours to take that gear box to pieces, and the whole trouble arose over two nuts of standard sizes. There were in the garage half a dozen spanners to fit each nut, though the kit supplied with the bicycle contained none. But each nut was so curiously and stupidly located that none of the special spanners available could get a hold. Each nut had to be punched off with a chisel, and, as they were light nuts, the job would have been held up to await the arrival of new nuts, if the nuts had been tight. Luckily, however, they were a trifle loose and came away readily. In no case was there the least reason for the awkward placing of the nut, and I could have redesigned the part to give an ordinary adjustable spanner easy access without any addition to the cost.

British riders are, of course, tolerably cynical in the matters to which the above paragraph refers. When they buy a new machine they take it for granted that they will have trouble in their repair and adjustment work, and they are rarely disappointed. Some of us regularly resort to professional assistance, and you may often see two or three mechanics kneeling on a part of a motor cycle on a garage floor whilst another tackles some immovable detail with a mallet and a tyre lever or other butcherlike combination of tools. Some of us gradually amass a wallful of assorted spanners, and can generally pick out something to suit a crazy designer's latest whim. We worry through somehow. But we have been talking very fine and large about our Overseas trade after the war. It has great possibilities, and is generally understood to depend upon our offering Overseas buyers a first-class machine at a reasonable price. That is only true as far as it goes. It is the first instalment of success. If we offer Overseas buyers a machine equal to our best pre-war mounts at a cost of £25 (which is, of course, impossible) we shall still lose our Overseas trade unless that cheap, high-grade machine is either perfectly adapted to management by its owner, or unless we provide what the Americans call "good service," *i.e.*, a sprinkling of live, sensible agents, thoroughly furnished with tools and spares. Most of our exported machines have been marred by one or more items unsuited to local conditions.



Current chat

Times to Light Lamps.

Women Motor Drivers for Home Service.

The Women's Legion is now giving free instruction in motor driving for Government work with free accommodation during training.

No More Men Drivers.

The idea is that all Government motor vehicles will shortly be driven solely by women, although we should imagine that some limitation is bound to be applied in the case of drivers for big lorries.

A Chance for Lady Motorists.

Any lady interested should apply to the offices of the Women's Legion, which are situated at 18a, Pall Mall East, S.W.1.

Coal Gas.

The Commercial Motor Users' Association has in course of preparation a list of gas-charging stations throughout the United Kingdom, and the first issue, containing some 1,000 names, will be ready shortly. It will be obtainable on application to the secretary, 83, Pall Mall, S.W.1.

The Local Taxation Licence.

We are receiving many enquiries from correspondents asking if it is necessary, in the case of a motor bicycle which is kept but not used, to dismantle any part of the engine or machine, so as to satisfy the taxation authorities that it is exempt from the tax. This is not necessary; the tax need only be paid in respect of a motor bicycle which is used at any time during one year.

Naphtha.

One of the most popular petrol substitutes in those days when substitutes could be freely used, although petrol was restricted, was "solvent naphtha." This is a substance belonging to the benzene series, and it bears to benzole much the same relation as paraffin (or kerosene) does to petrol. It is, of course, obtained as a by-product in the fractional distillation of coal.

All *dealing* in this substance is now forbidden except by Ministry of Munitions permit. The comprehensiveness of the new Order is indicated by its wording, "No one shall supply, take, accept, or attempt to obtain delivery." Is it a cause for thankfulness that this latest Order does not affect motorists?

Activity by an Automobile Body.

The A.A. and M.U. has urged to the Treasury that some modification should be introduced on motor taxation for 1918. The grounds for this representation are that limited fuel supplies will naturally severely restrict the amount of use to which motor vehicles may be put.

How to Cure Belt Slip.

A correspondent writes, with regard to belt slip on a 5 h.p. Zenith, that he was troubled with this form of annoyance a good deal with both rubber and leather belts until he fitted a leather mudshield. He is now able to ride on the worst of ordinary roads in the worst weather, and the belt is kept quite clean and dry.

Decarbonising an Engine.

A correspondent sends us the following wrinkle for decarbonising an engine. First soak the parts to be decarbonised for at least twenty-four hours in a hot solution of strong caustic soda, afterwards washing the parts in cold water (not forgetting to wash the hands); then dry them and insert them in a paraffin bath. After that any carbon then remaining is quite easily removed.

ENGLÄNDERLAGER, RUHLEBEN, GERMANY.
XMAS, 1917.
With Best Wishes for Xmas for 1918.
from T. Hilger

FROM RUHLEBEN.

A Christmas greeting card received from Mr. T Hilger, now a prisoner in Ruhleben. He inscribes the card, "How to keep cheerful—read the 'Blue un.' I still get it."

Special Features.

WIRING AN ACCUMULATOR LIGHTING SET.

THROUGH RUSSIA, TURKEY, AND ROUMANIA.

OUTSIDE FLYWHEELS FOR V TWINS.

Speed Merchant Honoured.

Capt. L. G. Hornsted, who in July, 1914, did 124 m.p.h. at Brooklands in a German car, has been mentioned in despatches.

Motoring in Holland.

It is stated that as a result of the petrol shortage all private motoring in Holland is to be forbidden, also a strict control of military motor vehicles is to be instituted.

And in Spain.

In Spain a similar shortage exists, and while, as far as we are aware, no definite legal restrictions are in force, the running of public service as well as of private vehicles is unavoidably much curtailed. The Government is on the point of introducing the English control system. Spain will wake up one morning shortly to realise what a terrible war this is.

Special Activities.

In Coventry on Thursday morning last—and possibly in other parts of the country—the specials were holding up every type of motor vehicle, whether car, lorry, or cycle, and demanding permits and petrol cards. No doubt many summonses will result. Personally, we were using coal gas when stopped, but this made no difference in the usual formula being followed.

There was a rumour afloat that the Coventry specials had demurred that no cars were being held up for an examination of permits, while there had been several motor cyclists summoned, at which the police replied, "Very well, then; you specials shall have a special day to yourselves, and stop every motorist you see." Needless to add, we very much doubt the truth of this report.

Identification Marks.

When a machine had been stopped, a small white disc, bearing the number of the special who had stopped it, was fixed to the front wheel mudguard. A party of testers were amusing themselves by sticking these discs on various obscure portions of their machines or their own persons, with the result that they were stopped again, and the entries duplicated.

What will be the next step in the process of elimination?

Century of Engineering.

On January 2nd the Institution of Civil Engineers completed the hundredth year of its existence, having been established on January 2nd, 1818.

An Extraordinary Smash.

On the Eltham Road, S.E., shortly before midnight recently, a motor lorry ran into a column of partly lame and disabled A.S.C. men, placed six *hors de combat*, then overturned. Someone rang a fire alarm that brought a motor fire engine and salvage car to the scene! On the latter the wounded were removed to hospital.

A Hard-worked Sidecarrier.

An early Bat sidecarrier, owned by the proprietor of the only store at Keston village on the Westerham Road, must have a lengthy service record. Daily and in all weathers the outfit can be seen with its veteran rider on delivery rounds in a hilly district.

A New Oilfield.

In these days of increased demand for motor spirit, it is gratifying to note that a new oilfield of considerable importance has been opened up about eight miles east of Los Angeles. It seems probable that about 2,000 acres will prove productive. One well put in by the Standard Oil Co. is yielding about 7,000 barrels a day from a depth of nearly 3,800ft.

Motor Cycle Messengers in the U.S. Army.

For conveying information regarding the dead and wounded of the U.S. Army in France, motor cyclists will be utilised to a great extent, and will carry the tidings over the first part of the journey from the trench and battle lines to the divisional headquarters. Messages will then be telephoned and cabled to Washington, whence the War Department Statistical Bureau will forward them. Through this organisation relatives and friends should receive news within two days, and possibly within twelve hours.

Methylated Spirit.

Owners of water-cooled machines are at this time of the year always concerned as to the safety of the radiator when the machine is standing overnight in an unheated garage. Various anti-freezing mixtures may be used, and one of the most popular of these is methylated spirit. An Army Council instruction recently published forbids the use of this medium in Army vehicles for this purpose. Last winter, in France, it was common practice to run lorry and other water-cooled engines all night, so as to make sure that they should not freeze, and, of course, incidentally, to avoid considerable starting difficulties in the morning.

Motor Cycles by Passenger Trains

We were informed by a well-known member of the motor cycle trade that the railway companies now refuse to accept any article weighing over 112 lb. by passenger train. Consequently only featherweight motor cycles are accepted, and all others must travel by goods train. This would necessitate their being packed in crates. However, when we recently rang up the Railway Clearing House on the subject, they informed us that they knew of no regulations preventing the carriage of motor cycles by passenger trains.

There seem, however, to be various new rules of which the officials themselves are not aware. In an out of the way village station over a year ago the stationmaster refused to accept a motor cycle for carriage by train. The machine was ridden twelve miles to a more important station, where it was accepted without question. A good deal seems to depend upon local congestion of traffic.

A Patriotic Motor Cycle Club.

Fifteen out of eighteen members of the Indian Motor Cycle Club, Chicago, are in training with the U.S. Army. The remaining three are exempt from service. This is certainly a very fine percentage.

The Italian Coventry and the War.

Turin is the motor manufacturing centre of Italy, and it is interesting to note that this town recently subscribed £300,000 in one day in aid of refugees from the territory now in the hands of the enemy. In addition, the 25,000 Fiat workers voluntarily decided to contribute one day's pay per month for six months to relieve distress caused by the invasion.

Collision between Motor Cycle and Aeroplane.

A curious accident happened at the Leeside Aerodrome, Toronto, on December 5th, when an aeroplane collided with a motor cycle and sidecar. This is the first mishap of its kind known. The accident took place when Capt. J. N. Bacon, R.F.C., was making a forced landing in a street in the vicinity of the camp. The propeller smashed the sidecar outfit, and instantly killed the corporal and air mechanic who were in it, while the aeroplane itself was seriously damaged. The motor cyclists were preparing to go to the assistance of the airman, who was seen to be in trouble.

The National War Funds.

The National Relief Fund (distributed £3,743,877)	£6,318,092	0	0
British Red Cross Fund	8,711,420	0	0
Tobacco Fund	146,083	0	0

Petrol for Motor Cycle Specials.

Lee special constables owning motor cycles have been informed they can obtain petrol free at the head station on the receipt of raid calls. The machines are used for giving warning and also the "all clear" signal, and can cover more ground than pedal cycles.

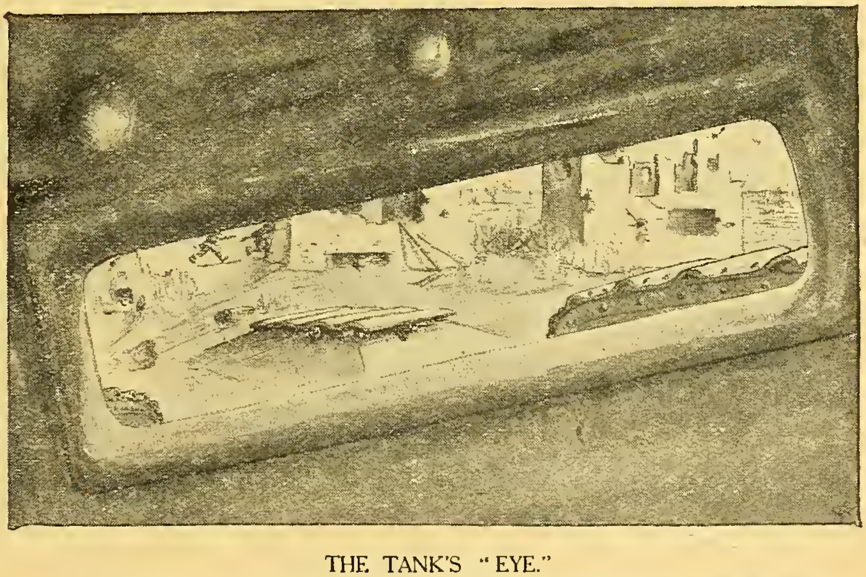
Smart Machines.

One of the smartest machines one sees undergoing test in the Coventry district at the present time is the new model 5 h.p. twin Rover, the red tank and green finish of which are extremely attractive. This machine has an all-enclosed chain drive, as our readers know, and looks a very enticing solo mount, though the handle-bar position appears rather high for perfect control.

Stop Thief!

It is not often that the Order of November 1st provides amusement, but we recently saw an incident at once amusing and exciting (!) caused directly by this motorist's sword of Damocles. A very old and noisy single-cylinder two-seater car was, with the hood up, rounding a corner in Coventry, when two Specials, standing on a refuge in the middle of a rather wide crossing, began shouting and wildly gesticulating for the car to stop. Whether deliberately or accidentally we do not know, but the driver took no notice, and his rattle box kept merrily on. One of the Specials then gave chase, caught up the car on the near side, and, seizing one of the hood sticks, swung himself in correct Yankee police style on to the running board, and ordered the driver to stop and justify his existence!

What surprised us most was the fact that the hood stick stood the strain to which it was so suddenly subjected, and we wondered what would have happened to the zealous Special had it given way.



THE TANK'S "EYE."

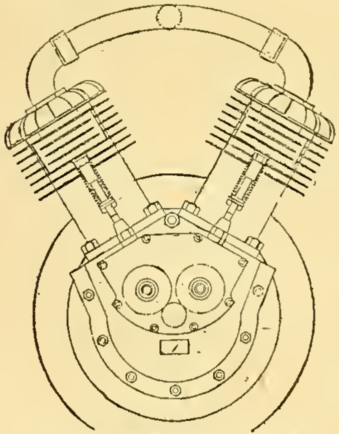
The drawing, which is from a sketch made by Pte. Eugene Fuller, now in Maidstone Hospital, illustrates the skill needed by drivers of the Tanks, the field of vision being so limited, and even this is not direct sight, but reflected through a prism.

OUTSIDE FLYWHEELS ON V TWINS.

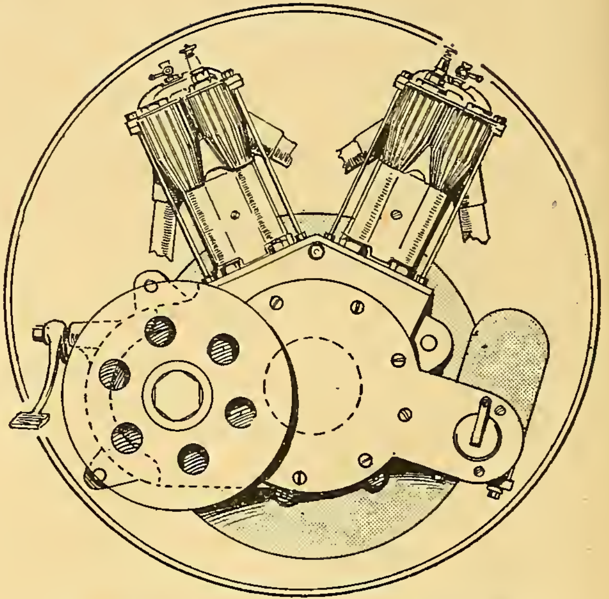
A Revival of Interest in the Question of Outside Flywheels on Engines of the V Twin Type.

A CORRESPONDENT who writes on a postcard and does not sign his name, so that we are unable to reply to him, says: "Why not a V twin with an outside flywheel? I cannot remember ever having seen this discussed in 'The True Blue.'" He signs himself "Since 1903," and yet in the issue of April 17th, 1905, there appeared a description of a motor bicycle made by Mr. Anthony Westlake, which had a V twin-cylinder engine provided with an outside flywheel 12½in. in diameter. The engine dimensions were 78 mm. × 90 mm., and the inlet valves automatic. Two sparking plugs were fitted in each cylinder, two outlets were provided for the exhaust below each valve, and two B. and B. carburetters were provided. It was specially built for the International Cup Race, but unfortunately never survived the eliminating trials. Its designer, Mr. Westlake, was the first secretary of the M.C.C. To the best of our recollection the early Clement-Garrard V twin was also equipped with an outside flywheel.

This anonymous correspondent's communication, strange to say, coincides with a very interesting letter from "Howitzer, R.G.A.," enclosing specification of a 50° twin with outside flywheel, and also with a letter from Mr. J. Graveson on a similar subject, and it would almost appear that for some mysterious reason interest in the V twin with even firing impulses and outside flywheel has suddenly revived. One point that seems to have escaped the notice of practically all the correspondents is that there is nothing fresh in the idea of the V twin with even firing impulses and an outside flywheel, and indeed so recently as 1911 the Premier Cycle Company, of Coventry, had on the market an excellent machine with a power unit of this type. The Premier twin enjoyed a fair amount of popularity, and was in every way a successful machine. It was commended in all quarters for its even running, silence, and sweetness of transmission, and among the advantages claimed for it by the makers were the reduction of the risk of skidding on account of the smooth torque of the engine; less tyre wear and tear, for the same reason; and also improved hill-climbing power. The accompanying illustrations show the complete machine, and also the engine of this interesting mount, which, it should be remembered, had several years before passed out of the experimental stage. It will be seen that there is nothing whatever freakish in the design of the complete machine, and that the power unit is very compact.



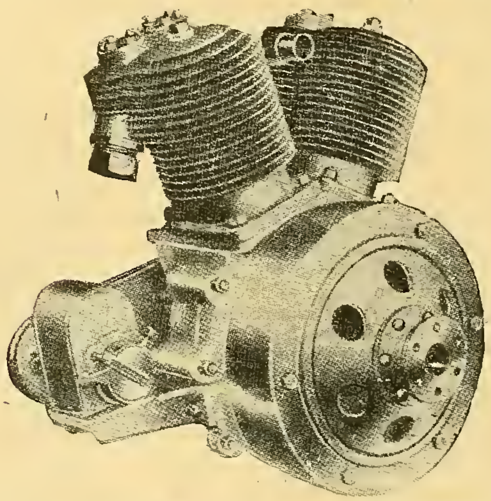
A V twin with outside flywheel, made by Anthony Westlake in 1905.



A design of a V twin with outside flywheel submitted by "Howitzer, R.G.A."

The letter from Mr. Graveson is as follows:

I had intended making a V twin motor cycle engine with outside flywheel after the same style as the horizontal twin in nearly every respect, but time has been against me, so I offer the idea (I have since found it is not quite new) to anyone who has a little spare time to work on it. The V twin can be made to fire at equal intervals, the same as the horizontal twin, by giving the crank the same amount of angularity as the cylinders (roughly). Of course, the crank will have to be of the double throw type, as in the horizontally opposed engine, and the cylinders staggered a bit to allow a direct thrust from the piston, but that would assist the cooling of rear cylinder.

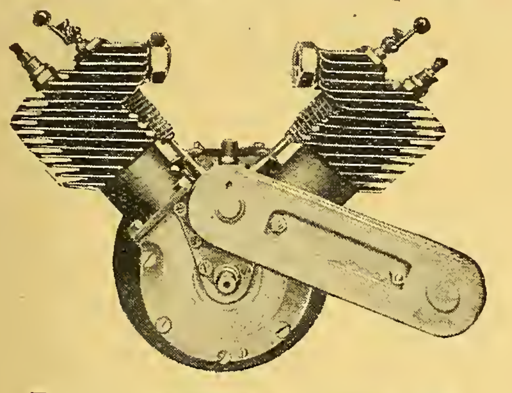


The Fafnir, 85 × 88 mm., having an additional outside flywheel in which was incorporated a clutch.

Outside Flywheels on V Twins.—

The advantages of this type would be the retaining of the present popular type of frame, lower centre of gravity [?—Ed.], and less cost to produce.

Balance should be as good as in a flat twin, and a little more or less angularity of the crank pin would give the desired balance. The size of engine would not be limited, as in the horizontal, and there would be ample room for gear box, etc., without unduly elongating the frame of the machine.



The 3¾ h.p. Premier twin first produced in 1909. The bore and stroke of the engine were 66 × 80 mm., the cylinders firing at even intervals

I should like to hear if anyone has tried this type, as I do not see any difficulty in designing the V to equal the horizontal in equal turning moment and vibration. The majority of writers seem to forget the Scott in their arguments, and it is rather surprising that no Scott riders have had a word to say during the controversy of the flat twin, as the Scott has undoubted advantages, which I will leave to the makers for elucidation.

It will be seen that Mr. Graveson recommends a 90° twin, which is after the style of the old Premier. "Howitzer R.G.A.," however, suggests a 50° twin, and illustrations of this engine and complete machine are reproduced in company with his letter, which, as it speaks for itself, we think we cannot do better than reproduce in full:

Sir,—I am venturing to enclose rough drawings of my ideal motor cycle, and would emphasise the fact that it is intended only for solo use, and would be advertised and sold for this purpose. The design is prompted by the following considerations:

1. A machine capable of taking a sidecar inevitably suffers as a solo.
2. Clutches are expensive, not always satisfactory or reliable, and, unless accompanied by a kick starter, rather useless. Kick starters are very seldom reliable, and at best very much more laborious to work than it would be to paddle off a properly made engine on an 8 to 1 gear.
3. Noisy valve gear and oil slinging are two vices common to every British motor cycle I have owned, except the poisonous two-stroke, which easily makes up in the latter what it lacks in the former.
4. Chain and belt drive involves carrying repair outfits for both, and the gear box must have room to slide. All chain drive calls for a shock absorber, which, though often perfectly satisfactory, costs money to make.
5. A tank holding 1.9 gallon is a permanent nuisance, and it is not dignified for a manufacturer to advertise the tank as holding two gallons when it does not.
6. Coned petrol taps almost invariably leak, while screw-down ones do not.
7. Breadth in the engine is quite immaterial if the tank be made wide in proportion, so as to keep the rider's calves from getting cooked.
8. The merits of the outside flywheel have been discussed *ad nauseam*, and are really overwhelming. They have made the Douglas famous, and even secured a brief toleration for the awful two-stroke.
9. I cannot personally discover any carburetter on the market to touch the Schebler for general efficiency and petrol economy. It has only two drawbacks, viz., its price and the fact that it demands a small amount of horse sense to get the best results from it.
10. The British maker says to himself, "I will now produce a machine of 500 c.c. and see what I can make it do." The purchaser says, "I require a machine to do so and so." Hence the two are at cross purposes *ab initio*.

SPECIFICATION.

Engine.—50° V twin, detachable heads carrying valve pockets and ports. Roller big ends and crank on tuning side a separate piece. Outside flywheel. Gear drive from flywheel side by herring-bone gears to Douglas pattern two-speed gear box, and by belt from off side of gear box. Gear shift by pedals protruding on each side behind gear box. Carburetter, Schebler, with twist grip control. Dimensions, 65×90 to 75×90, as found necessary. Valve spring covers screwed to bosses on crank case, and having leather washers to stop all leakage.

Tank.—Harley-Davidson pattern double tank holding two gallons in main tank and about half a gallon in small tank. Screw-down taps. Large fillers. Euk starter inside tank.

Wheels.—28×3.

Brakes.—Flywheel brake on near side. Rudge belt rim brake on off side. Both pedal operated.

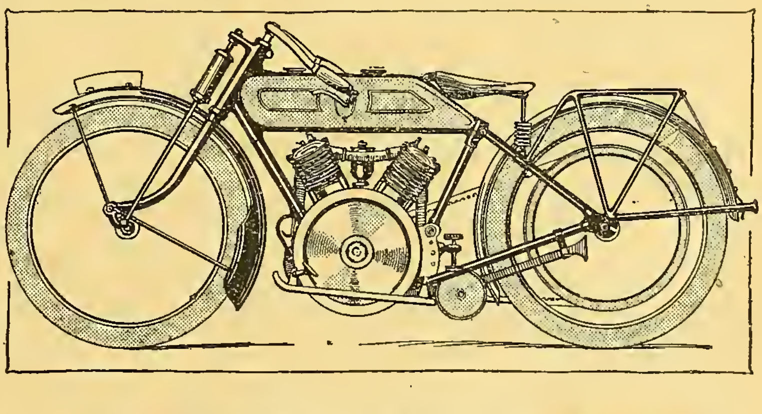
Saddle.—Pivoted on top tube springs to brackets on back stays.

Lubrication.—Hand pump with tap and intelligence.

Forks.—The old Druid is really just as good as any.

Lydd. HOWITZER, R.G.A.

These efforts at the outside flywheel on a fairly large size V twin machine are, of course, quite different from those big twins that have had an extra flywheel added on to the ordinary crank case which already has two internal flywheels. Only a few engine makers have deliberately fitted an outside flywheel to their engines extra to the two inside the crank case, other than in the case of the Fafnir engine, which had an extra outside flywheel, as shown. This flywheel, however, incorporated a clutch, and, of course, it is quite common practice to add a clutch and a combined flywheel on to a V twin motor cycle engine when incorporating this into any form of cycle car frame; in fact, nearly all cycle cars have a combined flywheel and clutch added on to the engine shaft. Certainly in this case the main object of the addition was the provision of a clutch, and the flywheel effect of this was quite incidental; nevertheless it was none the less present, and, we may say in passing, useful.



A V twin motor cycle designed by "Howitzer, R.G.A.," having several features of interest, besides the outside flywheel.

Letters to the Editor

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

ENGINE BALANCE.

Sir,—Would you be generous enough to spare a little space in your correspondence columns and insert the following query, which the makers have not answered? I have a single of great repute, 79×100, and when running fast there seems to be undue engine vibration. Now, there must be many riders of this type of machine who know their engines from A to Z. Could anyone tell me (*viâ* these columns) where the piston comes to rest? Mine comes to rest 47° from bottom centre, valve out and belt off of course. Wishing *The Motor Cycle* every success in the New Year and all the best of wishes. NORTONIAN.

Basingstoke.

GOODS MADE IN GERMANY!

Sir,—Your correspondent "R.O.W.," in your issue of the 3rd inst., states that, in his opinion, the notice which you print weekly is "unworthy of a sporting paper." Mr. T. Jones and his friends apparently take the same view.

Surely, sir, on reflection, these gentlemen must see that it is just the clean sporting and technical papers, of which *The Motor Cycle* is certainly one, which should take a strong line in the matter: quite apart from any question of politics, or economics, or trade after the war.

We Britishers have many faults, and this war has emphasised them in many ways, but one virtue is accorded us by general consent—we are clean fighters, and, in ordinary circumstances, are always ready to shake hands with the enemy when the fight is over. But we are now dealing with a foe who has furnished overwhelming proof of his bestial cruelty, his devilish methods, his scornful rejection of all the laws of humanity, his untrustworthiness, his cunning, and his hate. There is no need to give details. Who does not know them? We have to make that foe realise that he is not fighting as a clean sportsman, and when we have beaten him, as we shall, we have to teach him that foul play, which usually incurs penalties, must do so in his case.

If the Germans are "victims" to Prussianism, as "R.O.W." suggests, will he tell me how, or why? No, sir, it is within the power of the German people to overthrow Prussianism. Until they at least show signs of a desire to do so we must regard them as in sympathy with its vile methods, and, indeed, as active agents and co-operators. The German people must purge themselves of the evil which seems to have permeated every fibre of their being—every activity of their national life—before we can shake hands with them again.

Meantime, the proprietors of *The Motor Cycle* deserve the thanks of all true sportsmen for the stand they have taken in this matter, not least because it is evidently a line of action, which must mean a loss of advertisement revenue after the war.

I should like to deal at length with the commercial aspects of the matter, and, in particular, to tell "R.O.W." something about Bosch *v.* British magnetos, but space does not permit, although perhaps you will allow me to refer thereto in a later issue. BRITISHER.

London.

Sir,—As a free trader who wants the inhabitants of these islands to have access to the whole of the products of human ingenuity, and also as one who realises that we shall have to live along with the Germans after the war, I confess to sharing the contemptuous irritation of your correspondent, Chas. S. Ives, whenever I saw your announcement.

But I remembered that this non-party publication had but given, in a definite, forcible way, patriotic adhesion to the policy of an economic war after the war agreed upon by our national Government at the Paris Conference.

That policy, however, has recently been repudiated by Cabinet Ministers in the name of the Government. It follows, therefore, that the patriotism which gave birth to the objectionable paragraph now calls for its burial; and I am wondering whether you, in your wisdom, will ever allow us to see it again. H. LEAVIS.

[We commend to our correspondent a perusal of the pamphlet "Murder Most Foul."—ED.]

Sir,—Having read the letters of Mr. C. S. Ives and "R.O.W." *re* trading with the Hun after the war, let me ask these "so-called" Englishmen if they have ever met the Hun since August 4th, 1914. I am "one of those who went" in 1914, and have witnessed some of the German acts of "Kultur," and rather than earn my living in any way that would help or assist the Hun, I would sooner finish my life in the workhouse—aye, or even a prison.

Why encourage the Bosch when there are thousands of men "out there" who, with a little training, can turn out a magneto as good as, even better than, any German?

I have held a position in a large motor establishment—a position as sales manager—so have a little idea of the article in question.

May *The Motor Cycle* and all other motoring periodicals publish each week their resolution, as they have been doing, and so encourage articles to be "solid British," made by "solid Britishers."

The remarks in Mr. C. S. Ives's and "R.O.W.'s" letters are rotten to the core.

Wishing your journal every success,

Kingston. SILVER BADGE.

Sir,—I am astonished to think that there are men in this country, presumably British subjects, who are ready to trade with the unspeakable Hun at the expense of the British nation after the war! We have for some time past been only too familiar with the "Conchie" and the "Pacifist," and it is now with sorrow that we must add to these friends of the Hun yet another class—the followers of Mr. C. S. Ives.

One of the very points for which the Hun is now fighting is post-war trade, and it is up to the buyers of this country to see that he does not make advances on a wide front in the war after the war.

Does not Mr. Ives realise that the Hun is guilty of every indecent act, every immoral act, and every dastardly act imaginable? Yet he suggests that we should support him and fraternise with him after the war! Surely it is more seemly that the Hun should be counted as outcast and unfit for decent people to trade with as a punishment in a small degree for his many crimes.

I am sure you will not shed tears at the withdrawal of the subscription of one who, by his own admission, is willing to trade with the Hun.

I am equally sure that there are thousands who would throw your paper over if you did not follow the course upon which you have decided. We shall not want any magneto or any part of enemy manufacture after the war, as experience has already shown that British makers have nothing to fear from the enemy.

N. R. CHANDLER,
Hon. Sec., Derbyshire and North Stafford Automobile Club
(Motor Cycle Section).

TWIST GRIP CONTROLS.

Sir,—I should be glad if you could find room in your paper for the following appreciation of the twist-grip type of control as fitted to American machines. A majority of people harbour the mistaken idea that they are liable to twist when one does not want them to, *i.e.*, when going over a bad bump, etc. Motorists who have had the pleasure of riding machines fitted with the above type of control will agree with me that this is utterly fallacious. The steering as well as the throttle and exhaust lifter are fully under the rider's control. There are no fiddling levers to "wangle." Give *me* an automatic carburetter with twist-grip control, and an exhaust and spark control interconnected, likewise operated, thereby doing away with two levers. Provided they are packed with grease, they give very little trouble, much less than the existing levers with their attendant wires, etc. I should very much like to see British machines fitted with the above, as I hope they will be after the war. I should like to have your readers' views on these twist controls, as I cannot imagine why there is not a *single* British machine fitted with them.

L. MERLIN.

THE STRENGTH OF MATERIALS.

Sir,—I enclose particulars of some tests taken by myself. I regret that I am unable to give fuller particulars owing to lack of time, but it will be possible to analyse exactly how metal behaves under tensile stress from the graphs shown. The graphs were plotted automatically, and are not subject to errors of observation.

A. C. CASS.

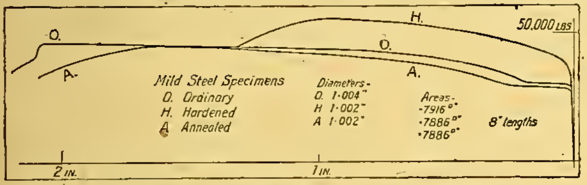


Fig. 1.—Tests of mild steel on an automatic machine.

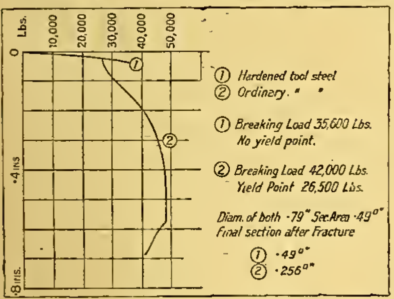

Fig. 2.—Facsimile of graphs plotted automatically on a 45 ton testing machine.

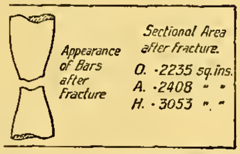


Appearance of Bars after Fracture
Sectional Area after fracture.
O. ·2235 sq. ins.
A. ·2408 " "
H. ·3053 " "

Fig. 3.—Fractured bar.

It will be seen that a load of 50,000 lb. has been applied before fracture takes place, although the breaking load is 42,000 lb.

TWO-STROKE RATTLE.

Sir,—An apparent cause of two-stroke rattle is that the rings passing the ports in the cylinder walls appear to be forced slightly into these ports, and give a decided noise when they are again forced into the piston. In an ordinary two-stroke engine there are found two piston rings on the upper part of the piston as a general rule—the top ring a compression ring, the bottom ring a wipe ring. The top ring is, as a rule, one of the hottest parts of a two-stroke engine, owing to the force of the explosion, and also owing to friction with the cylinder wall, as most of the oil is kept off it by the lower ring.

The average maker does not allow enough clearance between the two ends of the upper piston ring, which, owing to the high temperature under which it works, expands until the two ends press tightly together, thus endeavouring to cause it to take up more room than the bore of the cylinder; this causes undue friction, especially as it passes over the ports into which it frequently expands. After running a short time the ring usually gets so hot that it seizes up in the groove in the piston—as all two-stroke riders know.

The best remedy appears to be to use the lower ring as a ring to maintain compression, and use the upper ring as a wipe ring. I have obtained the best results by making the width of the top ring 75% of the width of the piston groove, and allowing when cold a gap of $\frac{1}{4}$in. between the two ends of the top ring. This does appear greatly to affect the compression, provided that the bottom ring is a good but loose fit.

I have cured numerous two-strokes of their rattle by this means, and considerably increased the speed of an Allon.

Solihull. LIEUT. R.F.C.

FLYING FACTS AND THEORIES.

Sir,—May I, in conjunction with "Commonsense," express the hope that Mr. W. G. Aston will again come forward to convince "O.J.F.S." and Mr. Brittain that their theories *are* wrong?

Although I have never met Mr. Aston, and only know of him from the very sound articles he contributes to various technical journals, I am perfectly willing to back him up in all his facts against the theories of "O.J.F.S." and others.

From the last issue of *The Motor Cycle* I am sorry to see that "O.J.F.S." is becoming angry. I do agree in one thing with this gentleman, that it is "an advantage when writing on a subject to have something more than a theoretical knowledge of it"; but, at the same time, "O.J.F.S." should beware of that little knowledge which is such a dangerous thing.

In the third paragraph of his letter he mentions something about getting off the ground with the throttle half open. This, of course, has nothing to do with the point under consideration. Then he goes on to state that "one can make a perfectly good climbing turn on some machines without having full throttle." Granted. And for the very good reason that the power output of an aeroplane is well in excess of that required for horizontal flight alone.

May I suggest that "O.J.F.S.," who hints that he is a pilot, should carry out this little experiment?

Let him take a machine to a couple of thousand feet, or higher, according to the state of the atmosphere, so as to get away from ground "bumps" and then fly level *without touching the "joystick."* In order to do this he will probably find it necessary to throttle down. Should he be on a machine with a hand adjustable tail plane he can set it so as to fly level. When he is satisfied that the machine is really neither climbing nor dropping let him start turning (using the "joystick" and rudder, of course), not a half-turn, nor a complete turn, but a continued turn. After a time he will find from the altimeter that he *has* lost height.

Should "O.J.F.S." be a moderately good pilot I would then advise him to try a climbing turn on one of those machines he talks about, provided that he has the controls set (throttle or tail adjustment or both) so that the machine flies level without his hand on the "joystick." If he then finds that he can make a "perfectly good climbing turn" let him continue his climbing turn, and be prepared for a stall, or maybe a spin.

These simple practical experiments should convince him that an aeroplane *does* lose height on a turn if no extra power is provided.

Regarding the fourth paragraph in the letter, "O.J.F.S." introduces the question of turns on the glide. Here again he has failed to grasp the sense of Mr. Aston's remark, which refers to "flying normally in a straight line," not gliding. The extra power required for a turn on the glide is very simply provided by gravity.

Irrespective of the fact that an aeroplane does tend normally to lose height on a turn, I think that the whole argument about turning down wind, especially near the ground, arises from the fact that pupils at R.F.C. schools are (or were) not given a sufficiently lucid reason for the warning. This warning is given because beginners consciously or unconsciously judge their speed, if they are low down, from terrestrial objects. The change in speed *relative to the ground* when travelling down-wind from that observed when travelling up-wind appears excessive, and there is thus a tendency for the beginner to imagine that the speed has increased through the nose going down too much on the turn. He then pulls it up, although the machine may be, and probably is, flying at its correct attitude, and a stall results, with disastrous consequences.

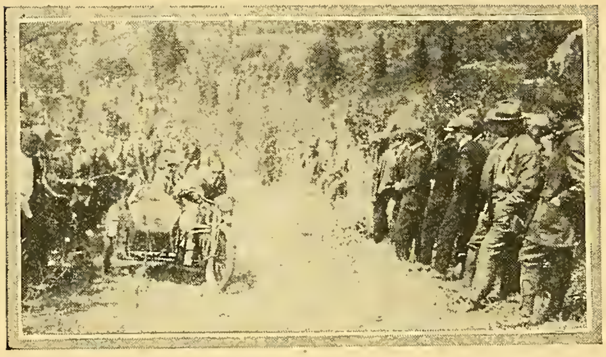
Perhaps, after all, "O.J.F.S." has all this time been laughing up his sleeve at the commotion his first letter caused. If so, I must congratulate him on the amusement he has given to so many of the R.F.C. PILOT.

Bristol.

AVERAGE SPEED IN U.S.A.

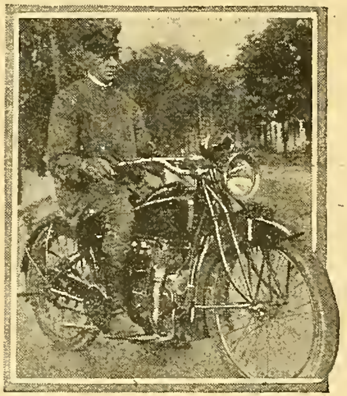
Sir,—Every so often we feel as how we just have to write you folks a letter, and this being one of them there now times, as it were, read the following. It may entertain; but, failing that, it will fill the page, so what's the odds?

It was sure laughable the way that average speed argument had everyone's goat a while back, the more so because it lets us know that you have lads over there who, when they straddle a motor bicycle and get a whiff of petrol in their nostrils, forget that there are sixty minutes to the hour and five thousand two hundred and eighty feet in a mile. We have a lot of 'em, too. Why a hombre had the nerve to tell us that he rode eight miles in eight minutes the other day on ordinary state highway! We merely asked him if he didn't stop for gas on the way and let him think he got away with it. Camouflage they call it now; but it's old stuff, the kinda bunk we'll always have with us, we 'spose. Why we rode ninety-three miles in three hours not long ago; but why brag about keeping out of gaol?



A scene at a hill-climbing competition at Newark, N.J., U.S.A.

Am sending you two photographs—one a scene at a hill-climbing competition last June, the other of a motor cycle policeman in our town. Since 1908, when three Reading-Standards were brought into the Department, we have had a motor cycle squad, and it has increased yearly. Yales, Excelsiors, and Harley-Davidsons have been used. The 1918 contract went to the latter make, and calls for twenty-eight machines—three-speed, of course, and electrically equipped. The men average from eight to twelve thousand miles yearly, and are on duty from 8 a.m. until 2 a.m. daily—that is, two shifts are.



A motor cycle policeman of Newark, N.J. His mount is an Excelsior.

The motor cycle police do traffic duty mainly, but assist in parades—riding solo and keeping crowds back being a regular job, take it from us. They are sent on special calls to outlying parts of the city, often arrive before the man on post can be located.

Besides the city force there are nine county police, who ride Indians, and maintain order in the park systems.

The motor cycle policeman may be found in many a small town as well, for it is a New Jersey State law that compels any officer to follow a speeder and compare the gait of the law violator with his speedometer. No speed traps, where a man is timed over a measured distance, will be permitted at all, the State law coming directly under the supervision of the Motor Vehicle Department.

E. B. HOLTON.

Newark, N.J., U.S.A.

EXHAUST POPPET VALVE DESIGN.

Sir,—May I reply to "D.L.E.," who criticises my remarks on De Lissa valves? I am very pleased to hear he has had no trouble with this valve. It at least bears out the well-known fact that identical engines do not always behave in the same way. I can assure "D.L.E." that the valves were most carefully ground in and that the timing was M.A.G. standard. Other timings were tried which, if anything, did behave worse. The compression in both cylinders was perfect. In fact, it was impossible to start without lifting the valves when using the kick-starter, and I think most of your readers will agree with me that there is not much wrong with the compression, and, incidentally, the valves in that case. "D.L.E." states that in his engine popping only occurs when the engine speed is too low for the load. Is he not confusing inlet valve blow-back with De Lissa valve popping? I never had a blow-back at all, but over 30 m.p.h. serious popping occurred, causing loss of power unless the air or spark were retarded. This was more pronounced with a Senspray carburetter than with an Amac. The only way to cure it was to increase the tension of the springs. This was most carefully done, and when the valves were closed it was possible to lift them easily about a sixteenth of an inch. When fully open it was impossible to move them at all, showing, to my mind, that the springs were too heavy—that is, the rate was too high. Weaker springs giving the same load at rest may have cured the popping without breaking the rocker arms. "D.L.E." states that the same size rockers are used in previous engines. Just so; I believe I remarked that there was bad design somewhere. Might I add to my criticism of exhaust poppet valve design of a previous issue that my remarks only referred to the illustrated examples, and only then because the air supply passages were totally insufficient.

Acton. OLIVOS.

FLYING IN A CURVED PATH.

Sir,—In your issue of December 13th, 1917, H. H. Groves, writing regarding flying in a wind, comes to certain conclusions, which are fallacies. I hope he will not mind my criticising his statements. He takes the conditions of a machine flying at 60 m.p.h. against a wind of 59 m.p.h., and states that if the machine be turned within its own length in order to fly down the wind the machine will have to be accelerated from 0 to 119 m.p.h., and that it will take time to produce this degree of acceleration. It will take time, but he infers that the time required for this acceleration will be greater than the time required to turn the machine when flying at the same speed in still air. For a given mass and accelerating force, acceleration is proportional to time. For a given mass and decelerating force, deceleration is proportional to time. If in a given time a given mass acted on by a given accelerating force has accelerated from 0 to 60 m.p.h., then in twice the time the acceleration will be double—that is, 120 m.p.h. If in a given time a given mass acted on by a given decelerating force is decelerated from 60 m.p.h. to 0 m.p.h., the same force acting in the same direction for twice the time will decelerate the mass from 60 m.p.h. to 0 m.p.h. in the first half of the time and accelerate the mass to 60 m.p.h. in the opposite direction in the second half of the time.

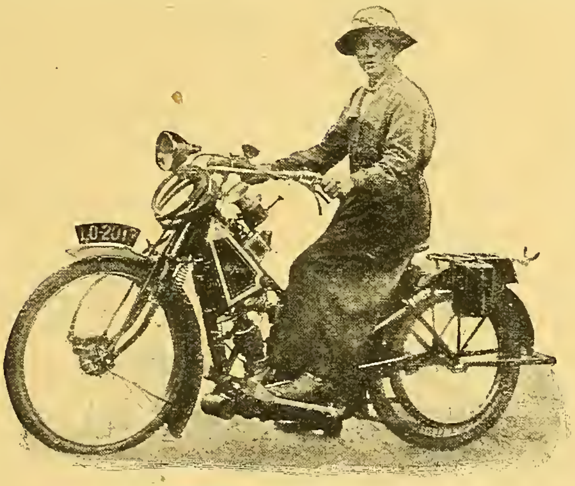
Take a different set of conditions—those of a machine flying at 60 m.p.h. in a wind of 60 m.p.h., and in a circle in the air of the same diameter as before. It will describe a semicircle in the air, but over the ground it will describe a volute curve such as a point on a wheel running on the road will describe in the air. The force producing the acceleration is obtained from the reaction of the air on the machine when banked for the turn, and is the same whether the machine is flying in still air or in a wind, provided the wind is steady.

With reference to the machine losing height while making the turn in a wind, it would lose the same height in still air. While flying level on a straight course the reaction of the air causes a resultant force acting vertically upwards equal to the weight of the plane. When flying in a curved path the centrifugal force is balanced by the reaction of the air. The weight of the machine and centrifugal force produce a resultant force acting outwards and downwards, balanced by reaction of the air. This resultant force, if plotted out, will be found to be greater than the weight of the machine. The plane is in effect thus more heavily loaded while turning, and for a given engine power developed must lose either horizontal speed or height as compared with its performance when flying straight and level. CHAS. WALMSLEY.

How a Lady Motor Cyclist's Knowledge of Machines was turned to Good Account.

WITH the passing of the erstwhile pleasure lady motor cyclist there has evolved a hardened and more practical rider, capable of strenuous effort and self-sacrificing patriotism. We shall always find a few mean individuals who evade the law, and, under the guise of national work, indulge in unnecessary riding, but these, we hope, are few. On the other hand, there are many who, with motoring experience gained most probably through joy rides before the war, are turning their knowledge to good account. Unknown and unostentatiously they "do their little bit" towards the stupendous whole that engages the attention of all worthy of the name of Britisher at this moment. One of these is the wife of Mr. T. Meeton, who carries on an extensive repair and garage business.

Before the war pleasure riding was the height of Mrs. Meeton's ambition. Learning to ride on a 7-9 h.p. Minerva some six years ago, she has since ridden almost all makes, and enthusiastically gives her vote of preference for a lightweight.



Mrs. T. Meeton on a 2½ h.p. O.K. Junior.

Lightweights Preferred.

A 2½ h.p., Mrs. Meeton thinks, gives all the necessary power for a lady riding solo. One feels master of a lighter machine, she says, and, although she is at home on a 7 h.p. Indian outfit, the speed and power are beyond modest requirements. An O.K. Junior, fitted with a M.A.G. engine, has given great satisfaction, and Mrs. Meeton is inclined to pin her fancy to this make. Her husband was a well-known figure in trials and competitions before the war, and his successes on a Rudge have materialised in a number of medals and a silver tea and coffee service given by the Surrey Motor Cycling Club in lieu of a number of awards. His wife has accompanied him as passenger in several contests, so the taste and sensations of speed are not unknown to her. Riding, however, at the present time has been supplanted by real hard work in the garage.

All vulcanising and tyre repairs are entrusted to her fingers. Taking engines down and decarbonising are now an open book to her. "Practice makes perfect," says an old adage, and this was never more true than in affairs motorish. A little knowledge is not always a dangerous thing.

Fitting New Covers.

Mrs. Meeton is fond of the work, and finds it interesting and not too hard, but the one job that she really dislikes is fitting new covers. Most of us know how stiff are the edges of heavy tyres, and how unyielding to any but the strongest fingers.

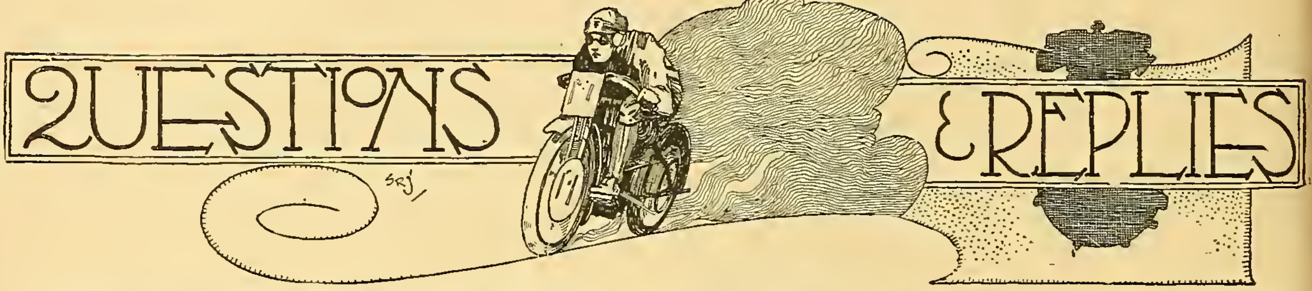
She has her own ideas as to a perfect ladies' mount, and is helping in her spare time to build a low frame around a Levis engine that her husband has purchased second-hand. The frame they have designed is very low, and neither really open nor diamond-shaped.

Mrs. Meeton is of small stature, and the machine is being built so that with ease she can reach the ground with both feet when astride. When I saw it the frame had been brazed, and was ready for the work with a file. Of course, the majority of motor cyclists do better to buy a machine direct from manufacturers who have long years in experience behind them, but still in the home-designed mount when successful the joy of parentage must add a good deal of pride to one's possession. Even a freak of one's own is preferable to the perfect machine of one's neighbour. Moreover, it is pleasant to find people of originality with sufficient enterprise to carry out their ideas.

A Projected Cycle Car.

Mr. Meeton has also obtained one of the few Buckingham engines, and when the war has ceased and the sun has set on the present insurmountable trade difficulties he will build round it a cycle car body in aluminium if his hopes be realised. The design is to be very similar to the Chota—a cycle car that is now obsolete.

MAY WALKER.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Two-stroke Timing.

I recently purchased a two stroke. (1.) What is the right timing? (2.) What is the cause of blowing back in the carburetter? I can run for a few hundred yards, and then the blowing back occurs, until it almost stops the engine. (3.) What size jet do you recommend? The present one is No. 24.—L.W.

(1.) The best timing for a two-stroke is as follows: Variable spark—Place the piston exactly on top of the compression stroke and connect up the magneto, with the points just broken and the ignition lever fully retarded. This will mean that the force of the explosion, when the ignition is fully retarded, will begin when the piston has travelled about 1.5 mm. down the firing stroke. Fixed spark—If for a hilly country, set the piston $\frac{5}{16}$in. below the top of the compression stroke, and if for a flat country $\frac{7}{16}$in. from the top; when in these positions the points should be in the act of breaking. (2.) Probably the cause is due to too large or too small a jet. (3.) We should recommend you to try the size smaller than the present one, and afterwards a size larger.

Lighting Systems.

I have bought a 6 h.p. twin A.J.S., and intend taking it to Australia shortly. I am anxious to have the best possible lighting set obtainable at present. I shall be using the machine solo for a great part of the time. Please tell me the advantages and disadvantages of the following: (1.) Electric dynamo and battery set. (2.) Electric lamp on accumulator alone. (3.) Electric magneto set. (4.) Prestolite or any other acetylene cylinder set.—K.C.W.

(1.) The dynamo and battery system is the best for a cycle and sidecar. It is expensive, but if made by a good firm it is entirely satisfactory. (2.) This system is quite satisfactory, except that the accumulator has to be charged from time to time. (3.) The magneto system is fairly good, but does not give so powerful a light as a proper dynamo installation. (4.) This is quite a satisfactory installation, but, so far as England is concerned, needs further development in the direction of motor cycles, as the cylinders are large and unwieldy. The actual Prestolite cylinder is not obtainable in this country, but it is possible you would be able to get it in Australia. If not, the set would be of no use to you.

Taking Machine Home.

Having purchased a motor cycle last October, I had to leave it in a garage for repair. Now the job is completed, I want to know if it would be an offence to drive the machine from the garage to my residence with petrol purchased with the machine?—J.B.

Technically you will be acting illegally in driving your machine from your garage to your house, but we do not think any bench of magistrates would convict under the circumstances. You might write to the Petrol Controller, who would in all probability grant you a special permit for the use of the machine on this occasion.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY.

During 1918 the restriction on the import of paper and paper making material is very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week

Stresses due to Passenger Carrying.

Which places the greater stress upon the engine whilst in motion (not initial stress upon starting)—a 12 st. man riding on the carrier or a 12 st. man in a properly sprung sidecar?—A.E.B.

As regards the actual stress due to the weight of the man, we do not think there would be much to choose between his weight on the carrier and his weight in the sidecar. On the other hand, his presence in the sidecar would very much increase wind resistance, and the sidecar alone (*i.e.*, empty) would exercise a much bigger drag on the machine than would the man on the carrier. Consequently, the more economical way of carrying a passenger would be on the carrier, but the difference resulting from the two alternative positions would be a difference due, not so much to the different position of the man's weight, but to the actual means employed for carrying him as a sidecar passenger. These remarks apply primarily to travelling on the level.

Unsatisfactory Deal at Auction Sale.

On the 20th of October, 1917, I bought in the local auction mart, sold by the auctioneer, a $3\frac{3}{4}$ h.p. solo motor cycle, guaranteed as a 1913 model in running order. I sent the engine and frame numbers to the makers, and they have informed me that the cycle was sent out from their works on March 30th, 1912. I informed the auctioneer, and he advised me to sell the cycle by auction as a 1912 model, and whatever it made less than £26—the price I paid for it—I could claim from the party that sold it as a 1913 model. I should be obliged if you could advise me.—G.M.

The advice the auctioneer has given you is quite sound. On the other hand, you could return the machine and demand back your money. We should advise you to settle the matter out of court if you possibly can.

Use of Petrol issued for Volunteer Work.

I shall be greatly obliged if you will kindly inform me how I stand as regards the use of petrol. I wrote to the Petrol Committee asking if it would renew my licence, stating I was a member of the local Motor Transport Volunteer Corps, and only used my machine for that purpose. The committee granted me a licence for twelve gallons, expiring on March 31st next. Am I allowed to take my wife for an occasional run in the sidecar; also, am I allowed to use my machine only on parade? Some people inform me the petrol is for tuning up purposes. As the machine is garaged in a damp place I should be pleased if allowed to take it out occasionally.—A.G.

If you have been granted petrol solely for use as a member of the local Motor Transport Volunteer Corps, you must not use this petrol for any other purpose whatever, unless the Commandant of the corps will give you an order so that you may say you are tuning the machine to prepare it for duty with the corps, and that, consequently, such tuning is on corps duty.

Petrol Licences for Soldiers on Leave.

Is there any likelihood of a private soldier being granted a short time petrol licence, whether on leave from the Front, wounded, or convalescent?—L.S.

There is just as much chance for a private soldier to obtain a short time petrol licence as there is for an officer, and if you write to the Petrol Controller your application will be considered, but you will understand that we cannot say definitely whether it will be granted or not. If possible, personal application at the Controller's office should be made.

Cracked Exhaust Valve Seating.

When overhauling my 1914 6-8 h.p. Rex, chain drive, I discovered that the front cylinder was cracked across from the exhaust valve seat to the inlet valve seat. Will you please tell me: (1.) Can it be successfully welded up? (2.) The tank is fitted with an Enots drip feed for the oil, but I cannot get the oil to drip. When I pull up the plunger of the pump the oil comes straight through the sight feed, even with the valve screwed in tightly. Please explain the cause. (3.) The clutch is a cork inset type. Should the insets and plate be free of all oil and grease?—F.W.

(1.) Yes, such a crack can be quite satisfactorily welded. (2.) Evidently the valve of the drip feed is not seating properly. It should be removed and entirely dismantled, and all parts examined to see if anything is preventing the valve from seating when it is screwed right up. (3.) Yes, it is advisable to see if the clutch is free from grease. It is unnecessary to lubricate a clutch of this kind.

Free of Duty Petrol.

I am using a 7-9 h.p. Indian and sidecarrier with my name, address, and business printed on it in 2in. letters both back and front, and the machine is used for business purposes only. The petrol granted me for the use of this machine and a Wall tricar, with a commercial box body, has been thirty-six gallons a month, duty free since August 1st, 1916. Since my last application for the renewal of this licence the committee say "that as some of this petrol has been used in the Indian I have infringed the Order, as they consider that it is liable for the licence duty, and therefore request the sum of £2 1s. 6d. for the extra 6d. per gallon duty on the petrol." Unfortunately, I paid the licence duty of £1 during the year. Is the Indian liable for the licence duty?—J.T.

We consider that the Petrol Controller's Department is quite in error. The fact that the machine has a sidecarrier and is constructed for the conveyance of goods and merchandise renders it exempt from payment of the local taxation licence; but we are afraid you have rendered yourself liable through having paid this tax, as no free-of-duty petrol is granted for use on a vehicle on which the local taxation licence duty has been paid. Therefore, we fear you have no alternative but to remit the amount demanded.

Back Firing.

I have a 6 h.p. three-speed A.J.S. with sidecar. It has just lately taken to backfiring when started up by means of the kick-starter, acting the same way whether the engine is cold or hot. It does not always do it, and altering the magneto so as to retard it does not make any difference whatever. I do not know if the magneto itself has slipped at all, but I had an accident the other day and ran the machine on to the grass by the side of the road, and eventually landed in the ditch. The machine apparently had not received any damage, but the magneto may have slipped on its bed, though the engine did not backfire when I started up after the accident. Another thing that puzzles me is the oil feed. If while the engine is running I turn down the little tap on the pipe leading from the oil tank to the pump, the pump handle is forced upwards from the barrel, and then it is possible by forcing it down to give the engine oil; but if I then turn the tap off, the pump does not recharge itself, nor is it possible to pull up the handle. The only way to recharge the pump is to turn the tap down. Is not the engine then sucking the oil straight from the tank as fast as possible? What I have been doing so far is to turn the tap down until the pump is full, then turn it off again until I want to give the engine oil, when I once more turn the tap down, force the plunger down, then let it get slowly refilled, and then turn the tap off again in order to prevent the tank getting drained. Is this how it should work?—E.A.B.

You should check your magneto timing. If the magneto was moved slightly by the accident to which you refer the only way in which the timing could be effected would be by the slacking of the chain, which would retard the ignition. This would have the opposite effect to causing backfiring, unless by backfiring you mean popping in the silencer. We rather imagine you mean that the engine kicks back, which is most probably caused by an excess of carbon deposit. As regards lubrication, all you have to do is to turn the tap down and force down the plunger, say, every five miles. You need not touch the tap again until you have finished with the machine for the day, when it should be turned off so as to preclude any possibility of leakage. If you desire at any time for the oil supply to cease while you are running, push down the handle on the pump and lock it with the device provided for that purpose.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

Aluminium Cylinders.

(1.) Could you tell me if the 3½ h.p. Norton with three-speed countershaft gear and kick-starter could do 60 or 70 m.p.h. if tuned up for speed? (2.) Would an aluminium cylinder fitted to a Norton be satisfactory for speed work? (3.) Do you think I would get any better results than with an iron cylinder?—G.R.M.

(1.) Yes; we should say that the machine should attain this speed if properly tuned up. (2.) We should say so; but we have had no practical experience with this type of cylinder at the present time. (3.) Theoretically, an aluminium cylinder should be more efficient than a cast iron cylinder on account of the better cooling properties of the metal.

READER'S REPLY.

Hub Gear Kick Starter Trouble.

I see in the issue of 20th December a query from "A.R." *re* kick starter of a Mark VI. Armstrong hub slipping. I have just had the same experience, so am forwarding the result, in the hope that it may be of use to your correspondent. My 'bus is a 2¾ h.p. Humber with Armstrong Mark VI. three-speed hub and clutch. I had thoroughly overhauled the gear and replaced it, when I found, just as "A.R." did, that the pedals would turn the engine slowly, but as soon as I pedalled hard to start the engine they slipped. I knew the free-wheel gear was all right, so I had a look at the controls, and found that the elbow piece at the end of the axle was screwed up one turn too much, thus preventing the top gear from engaging fully. This was the sole cause of the trouble, and, I think, of your correspondent's also. I shall be glad if this solves the difficulty, as I have had many useful hints from the pages of *The Motor Cycle*. Congratulations in passing on your attitude *re* "Goods Made in Germany." Hope your publisher did not swoon away when he heard that Mr. Chas. S. Ives had countermanded his order!—G.H.R.C.

RECOMMENDED ROUTES.

LIVERPOOL TO YARMOUTH.—C.A.T.

Liverpool, Warrington, Knutsford, Macclesfield, Leek, Ashbourne, Derby, Nottingham, Grantham, Stamford, Wansford, Peterborough, Wisbech, Downham Market, Swaffham, Dereham, Norwich, Acle, Yarmouth.

IPSWICH TO LEEDS.—B.B.

Ipswich, Needham Market, Stowmarket, Ixworth, Thetford, Mundford, Stoke Ferry, King's Lynn, Long Sutton, Swineshead, Sleaford, Newark, Tuxford, East Retford, Doncaster, Wakefield, Leeds. Approximately 180 miles.

BIRMINGHAM TO NEWCASTLE.—A.H.

Birmingham, Sutton Coldfield, Tamworth, Ashby-de-la-Zouch, Castle Donington, Nottingham, Mansfield, Worksop, Tickhill, Doncaster, Ferrybridge, Aberford, Wetherby, Boroughbridge, Northallerton, Darlington, Neville's Cross, Chester-le-Street, Newcastle. Approximately 200 miles.

The Military Norton.

We have been requested to state by the Norton Motor Co. that military model Nortons cannot be purchased without a Government permit.

Motor Trades Debating Society.

In consequence of many of the members being engaged on National Service and the early prospect of rationing, the committee has reluctantly decided not to hold a session this season.

Soldering Aluminium.

We have received a small aluminium box which has been soldered with ordinary solder by means of a special flux invented by H. C. Procter, of Levenshulme, Manchester, who assures us that this flux enables aluminium to be soldered to copper or other metals.

Spring Terminals.

A neat terminal which readily snaps into the neck of the milled nuts fitted to all Forward plugs is now marketed at one shilling per set of four. By its aid the high-tension cable is easily and quickly fixed, and the time spent in removing or fixing the milled nut is saved.

Waterproofs.

Burberrys are organising their New Year's sale from January 1st to February 28th. We have received their lists, and note that there are some excellent bargains in the well-known Burberry motoring garments, both for ladies and gentlemen. These sale lists, which contain full particulars, prices, and measurement forms, may be had on application from Burberrys, Haymarket, London, S.W.1.

A New Zealand Firm.

Our readers will remember previous references to Mr. J. B. Clarkson, who has often visited this country in the interests of the Oversea motor cycle business. The title of his firm is now Hope, Gibbons, Sons, and J. B. Clarkson, Ltd., Wellington, New Zealand.

This firm has decided to open an office in Sydney, Australia, in order better to look after the interests of the manufacturers whom they represent in that district.

A Carburetter Booklet.

Messrs. Brown and Barlow, Ltd., of Witton, Birmingham, have recently issued an entirely new edition of their handbook on motor cycle carburetters, and this edition surpasses all the firm's previous efforts in this direction. Readers may recollect that we reviewed rather fully a previous edition of this handy little booklet, and commended the hints and tips contained therein to the careful perusal of all motor cyclists, whether riders of baby two-strokes or of big twins. What the writer of this little book does not know about carburation in all its branches is hardly worth knowing, and the new edition has not been written merely for the sake of exercising his pen. It contains much new information, and may be had for the asking. The booklet is attractively got up, and, besides the information capable of general application, contains full illustrations of all types of B. and B. carburetters and their component parts.

SPARKLETS

New Tyre Depot.

We are informed that Palmer Tyre, Ltd., have moved their premises in Birmingham to Broad Street Chambers, where are installed their new showrooms, depot, and offices. All local enquiries should now be sent to this address.

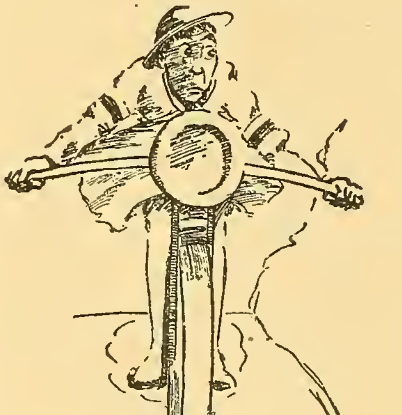
Insufficient Address.

Messrs. F.R.S. Lamps, Ltd., 7-9, Pershore Street, Birmingham, inform us that they are constantly receiving letters from members of our forces, both at home and abroad, which give an insufficient address. They state: "We do not know why this omission should be so general to khaki, but it is."

Review.

An attractive little book, tastefully illustrated and well written, describing the history of the Eagle and British Dominions Insurance Co. from its foundation, "Links with the Past" is well worth reading, giving as it does the history of insurance from the very earliest days down to the present time, when the latest and most recent form of insurance is that applied to motor vehicles.

The mechanically minded will find the chapter on fire engines interesting, as it deals with the old system of extinguishing fires by means of buckets down to the manual machine, and finally to the petrol-driven fire engine with which the L.C.C. Brigade is now equipped.



A humorous Christmas card received by the Editor. It is briefly inscribed—"From 'O' Corps, D.R.'s, B.E.F."

1918 Calendars.

Messrs. Prices' Co., Ltd., Battersea, London, S.W., the well-known lubricating oil manufacturers, have sent us some specimens of their 1918 pocket calendars, which are tastefully printed and delicately perfumed. They are of a very convenient size for carrying in a purse or pocket book.

Changes at Dunlops.

The Dunlop Rubber Co., Ltd., announce the undermentioned rearrangements in *personnel:* Mr. L. M. Bergin relinquishes the position of general manager and becomes managing director; Capt. George DuCros becomes general manager, with a seat on the board; Mr. A. H. Huet, late superintendent of depôts, becomes assistant general manager, Mr. W. H. Paull development superintendent, and Mr. E. H. Blake sales manager.

The Cygnet Rear Car Co.

We have already described and illustrated the Cygnet rear car, and we are now informed that, owing to the success of this contrivance, a new company has been formed for its manufacture under the title of "The Cygnet Mfg. Co., Inc." The offices and works of this new concern are still at 1200, Niagara Street, Buffalo, N.Y.

We are informed that these rear cars are being put to a fair number of military uses, and we must confess to being somewhat surprised at the information. The company itself is surprised at the success of its "limousine model."

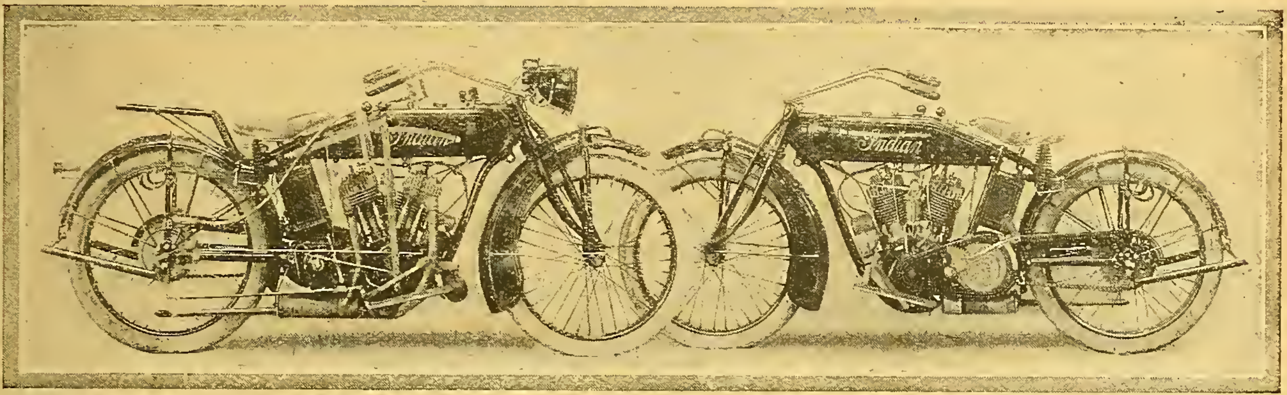
Hints on Repainting Motor Cycles.

At the present time, when it is so difficult to get work of all kinds accomplished, some hints on re-enamelling motor cycle frames and sidecar bodies will undoubtedly be welcomed by our readers. Messrs. Jenson and Nicholson, varnish and japan manufacturers, Goswell Road, Stratford, London, E.15, have issued leaflets giving instructions on cycle enamelling and also the enamelling of car bodies, both of which will be of valuable assistance to our readers in renovating their motor cycle frames and wheels and also their sidecar bodies.

People are prone to think that painting is an extremely simple matter, and that merely applying the paint with a brush will effect good results. This, however, is not so, and it is most essential that the article to be painted should be scrupulously clean. Secondly, the art of laying on the paint is not easy to acquire. The mere dabbing on of the paint with the brush will not produce the very best effects. The great art in painting is to apply as little as possible, and, to use a painter's term, work the brush right out. This is done by dipping the brush a little way into the paint and quickly laying it on the article roughly until the brush ceases to leave any mark. When the surface to be painted has been treated in this manner all over, it requires "laying-off," which means working the brush the whole length of the surface in perfectly straight lines until the part treated appears perfectly smooth and even. The paint will then dry evenly.

With Robbialac it is possible to get a surface almost as good as stove-enamelling, but it requires patience and care in use.

1918 Powerplus *Indian* Motocycles



Which we trust will be Post-War Models.

We regret that we are not in a position to supply motorcycles or send out catalogues at the present time, but when we are able to do so we will freely advertise the fact. This applies to Great Britain only.

OVERSEAS

OWING to the factory being engaged on Government work, we are still unable to supply for civil requirements, but it would pay you to keep in touch with us. Let us record your address for new list when ready.

Our post-war programme provides for a New Colonial and Sidecar 6 h.p. Twin Model with spring frame. Also Overseas Engines and Complete Sets of Fittings for the Home and Export Trade.

THE OVERSEAS MOTOR CO., LTD., 1a, Johnstone Street, Ladywood, BIRMINGHAM.

Hazlewoods
LTD COVENTRY.

We are busily engaged in munitions, but, as soon as things in Europe are put right, we hope to fulfil our obligations to our numerous clients. Meanwhile, write and have your name booked for earliest possible delivery.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

The Forward 1/6

Two Points

that should stand out in the service of a fastener are — long wear and reliability.

FORWARD

fasteners embody those two points to a remarkable degree because, first, their roller bearings distribute the wear evenly and not on one side; secondly, the steel links are of unusual strength and will not break.

The long life, efficiency, and dependability which result from such a combination are yours to test.

Will you do so? First write for full details.

The Capture of the German Dye Secrets.

THE recently announced achievement of the English dye trade experts in capturing from Switzerland the carefully guarded German dye trade recipes is an event of more importance to motorists than most of them will probably have realised. The use of aniline dyes is directly due to an English discovery that has been thoroughly exploited only by our greatest trade rivals—as has been the case only too often. It is now many years ago that an Englishman discovered the beautiful colouring matter to be obtained from certain of the anilines—by-products in the fractional distillation of coal tar—and his discovery was quickly taken advantage of by a German syndicate who soon established the enormous dye trade in which Germany easily led the world.

The development of this trade was directly due to the encouragement it received at the hands of the German Government authorities, who were quick to perceive the double advantage likely to accrue from the successful development of the new industry. Besides the natural advantage following to any nation from the acquisition of a great industry, this new trade had an entirely additional recommendation—it provided a field for the employment of those members of the benzene series that were obtained in the manufacture of coal tar, and that had hitherto been something after the nature of a waste product on the markets.

But the German Government saw further ahead than this, and many were the expressions of surprise in other countries when it was remarked that the Kaiser was showing an enormous interest in the industry. Not till the war broke out was the full secret revealed—*the benzene products were the main source of our most useful modern explosives!* Consequently by developing and encouraging the dye trade the German Government had also developed the most valuable possible resources for the war for which they had been so long waiting.

But besides the uses of the benzene series as a source of explosives—of T.N.T. to be precise—it is, of course, a most valuable fuel, and one that many motorists prefer to petrol. It will be remembered that long before there was any talk or suggestion of a petrol shortage all benzole had disappeared from the market because it was wanted for the making of explosives; it may also be remembered that one of the excuses put forward for the shortage of ammunition at the beginning of the war was the shortage of explosive material—in other words, of the raw material (benzole) for the manufacture of those explosives.

Now had this English invention of the aniline dye trade been kept in England by our Government as eagerly as it was introduced into Germany by the German Government, the relative positions of the two armies at the beginning of the war would have been reversed—we should have had an abundance of explosives and the Germans would have been short of them.

Now all this points to the enormous importance that should be attached to the magnificent achievement that has brought to these shores the incentive to our benzole producers to produce in large quantities. Their output will be developed primarily with the idea of meeting the requirements of the newly-established dye trade, but in the case of a national crisis it may be assumed that our then governing body will have the acumen to follow German precedent and to divert the greater part of the dyers' raw material into the fuel tank and the shell.

It may perhaps be as well to point out in conclusion, for the benefit of those of our readers not familiar with the nature of the benzenes and benzole, that the requirements of the shell factory and the motor tank do not exactly overlap, and that consequently there will be no ground for the assertion that the tank is being filled at the expense of the shell.

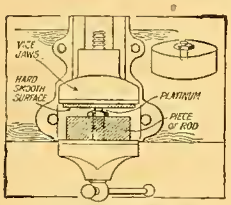
IDEAS: Useful and Ingenious.

SQUARING PLATINUM POINTS.

WHEN the platinum contacts of the make-and-break become pitted or do not meet squarely, a better way to deal with them than filing or hammering is this. From the "odds and ends" box, which most amateur mechanics have, get a thick bit of rod—the bigger the diameter the better, but not less than $\frac{1}{2}$in.—then make a central hole at one end into which the platinum screw will comfortably fit, resting with its head against the face of the rod, both faces of which must be square. Put screw and rod between the jaws of a vice, the platinum butting against a flat and smooth piece of hard metal, as shown in the figure. Squeeze the platinum against this metal surface in the vice, and the point will be flattened out as good as new.—H.A.C., Eastbourne.



Squaring platinum points without the use of a file or hammering.

TESTING SPARKING PLUGS

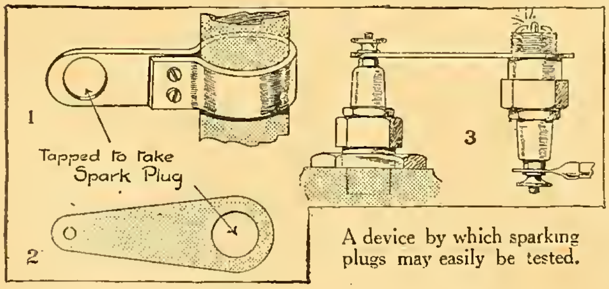
I AM submitting sketches of two plug testers that may perhaps be of interest. They are quite simple and inexpensive to make, and I have used them very successfully on cars and motor cycles for some years, finding them especially useful when reissuing used plugs for further service.

Fig. 1. To test plug for sparking, remove plug from cylinder, and with high-tension wire attached screw into hole provided in tester. The engine can now be revolved without any risk of plug falling—the usual result when it is balanced on some part of the machine by the old and exasperating method.

Fig. 2. This is a fitting for testing and showing the strength of spark at the points of a plug at any engine speed with the engine running with a good plug in the cylinder. The engine can be stopped and points adjusted any number of times until plug is giving its hottest spark. A number of plugs can be tested in a very short time with this device.

To use as shown in fig. 3, make sure that plug to be left in cylinder is working correctly. Remove terminal nut and high-tension wire from the plug, slip on tester, replace terminal nut and tighten. Screw plug to be tested into hole provided at other end of tester; attach high-tension wire and terminal nut.

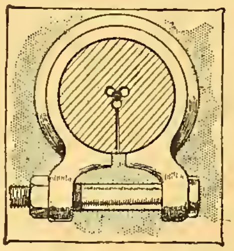
If this plug is O.K. the engine will run, and spark can then be observed and engine stopped for adjustment of points if necessary. If engine will not start, the points of plug to be tested can often be adjusted to spark correctly. I have not found this method of testing to have any injurious effect on the magneto, and it is a very fascinating operation to watch the spark dancing round a three-point plug.—D.R.C., Cardiff.



A device by which sparking plugs may easily be tested.

IMPROVISED SCREWING MACHINE.

FOR those who do not possess a screwing machine, spokes can be tightly fixed in a 1in. head clip, a screwed rod being utilised in place of the bolt. — Y.Q., Rouen.



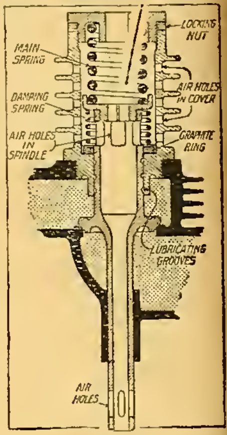
Head clip showing die in position.

DESIGN FOR EXHAUST VALVE.

SOME time ago an article suggesting the need for improvement in the design and construction of exhaust valves was published which gave a number of suggested improvements. Your criticism of some of the defects of these designs leads me to submit the following idea:

The design consists of a tubular spindle which carries the usual mushroom exhaust valve. Slots are cut in the spindle at the top and bottom ends to allow a free circulation of air for cooling purposes. The usual valve cap is replaced with a metal casing, made preferably of aluminium or gunmetal having radiating cooling fins, and being perforated with a number of holes for the passage of air through the valve spindle and round the springs.

In order to secure quiet running, two springs are suggested, the strong spring on the top being necessary to close the valve, and a light spring being placed underneath, to damp the sudden closing of the valve due to the strong spring, and to prevent undue noise and damage to valve seat. A locking nut has been provided to enable the load on the springs to be adjusted, thus permitting allowance to be made for the difference in the material, etc., in the springs themselves.



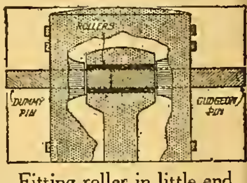
A suggestion for cooling the exhaust valve.

In order to secure lubrication of valve guide, and to prevent loss of compression, a graphite ring is placed at the top of the valve guide and held in place by the light spring. Lubrication grooves are turned on the body of valve guide, and as the graphite wears these grooves would become filled with graphite and tend to reduce wear and loss of compression to a minimum.

Of course I do not claim this to be an ideal design, but I think it has great possibilities for securing a really cool running and silent exhaust.—GEORGE E. BARR, Southsea.

ROLLERS IN LITTLE END.

TO insert rollers in little end of connecting rod, obtain a piece of steel shaft which is a loose fit in the gudgeon pin boles of the piston and about $\frac{1}{32}$in. or so shorter than the distance between inside face of bosses in the piston. Place the rollers and dummy pin in position in the connecting rod, and put piston in position also; then, when the gudgeon pin is tapped into place it will push the dummy pin out and, of course, maintain rollers in required position.—A.H.C., Coventry.



Fitting roller in little end of connecting rod.

OCCASIONAL COMMENTS.

By "IXION."

How Many Gears?

I SEE a friend is tilting at me for implying that four gears are not desirable on every motor cycle, so I must expound my position more perfectly. Motor cycle design is a matter of compromise. The nicest transmission I ever sat over—granted suitable road and weather conditions—was a countershaft Zenith with its ratios infinitely variable from about 4 down to 11 or so. Why does not every designer fit this drive? Not because it is patented—oh dear no. There are ways of dodging round almost any patent, and annexing the kernel of the device for yourself, whilst leaving the disgruntled inventor a disguised exterior at which to stare; our columns often contain ingenious illustrations of the plan. The Zenith transmission is not copied because it embodies a belt, and eke a belt with the minimum pulley diameter at the moment when maximum pulley diameter is desirable, to wit, when the load is greatest. So in the special interests of hill-climbers, sidecarists, and that type of amiable lunatic commonly known as an "all-weather rider," or "a hardy lad," other makers adopt the chain drive in lieu of camouflaging the Zenith patent by fitting the gear lever with a brass stirrup handle instead of the Zenith nickel knob. As soon as you adopt the chain, infinitely variable gears recede to the distant horizon with what Beatty calls "poor visibility" thrown in: and instead of umpteen gears we get a beggarly two, three, or four.

Two, Three, or Four?

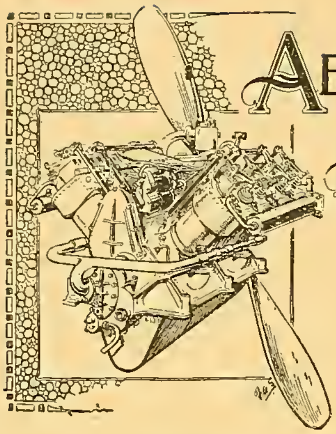
NOW my preference for two, three, or four gears reminds me of a hoary chestnut, viz., the Parliamentary candidate who rashly pledged himself to give a straight answer to a straight question, and was promptly asked whether he was a bigger fool than he looked or looked a bigger fool than he was. I cannot answer the alternatives by inditing a digit. It depends partly on the quality of the gear box. I would rather have a single gear than regain certain gear boxes which survive profanely in my memory; indeed, I would rather not own a motor cycle at all than accept one or two gears I wot of as a free gift. If anybody offered me a perfect six-speed gear box weighing 5 lb. I would give it instant preference over any gear now on the market. In actual fact, the more gears one specifies, the heavier and the more expensive the machine becomes. If you are rich, price doesn't matter. If you fit a sidecar, weight does not matter, as the machine supports its own weight. If you ride solo and have to wheel the jigger with one hand, whilst the other is more profitably employed on the far side of the waist of your latest fairy, unnecessary weight is an intolerable incubus, and so on. Adjusting these facts which determine the compromises, I arrive—and so, I suppose, do most people—at some such position as this. For a sidecar four gears are desirable. For a heavyweight touring mount de luxe, purchasable by strenuous people, a four-speed box, consisting of two close-set top ratios, a normal hill-climbing gear, and a reserve tree-climbing gear, is very nice indeed. For medium and light solo work, three gears are ample. For really light fast road work, two gears will do all that the hotstuff mount asks, and no hot-stuffer has ever yet appeared with the perfect hot-stuff two-speed gear.

The Motor Bicycle a la Ford.

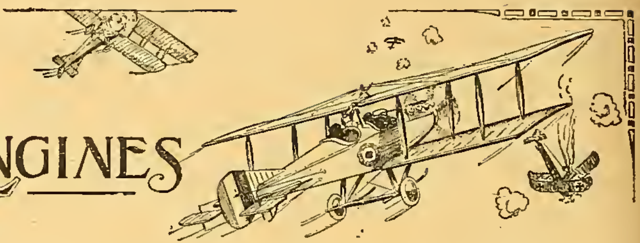
MY critic is perfectly correct in stating that I do most of my riding on a four-speed box, and that from time to time I give it free advts. of a somewhat fulsome character in this column. The machine in question is frankly designed as a heavy tourist mount de luxe, and it would be absurd to criticise it from the standpoint of Miss Shirley Kellogg doing a Park stunt on an auto-scooter, with brand new *chaussures* in evidence and a cinema man handy. When I wrote enthusiastically of two-speed gears, I had been musing on the following very sound lines. Prior to the war, motor cycles were chiefly built for buyers who had money to burn. The average motor cyclist is a person who has recently lost a relation with more money than brains. He has had a small legacy, which would have been far better devoted to a dogs' home or to a fund for providing Crimean veterans with decent baccy instead of shag. As money does not particularly matter to most buyers of motor cycles, motor cycles are designed and built accordingly; and their average pre-war price was at least £70. I even know many maniacs who have paid over £130 for a sidecar outfit. Now these are truly absurd prices to pay for a single-seated locomotive. I hope I may never even be carried to a casualty clearing station in a state of unconsciousness on a Ford car; but let us remember that in America an artisan can purchase a five-seated car in return for eight weeks' wages. In a world where you can buy 20 h.p. five-seated cars for £80 the continued existence of motor cycles averaging £70 apiece, as the standard of the world's markets, and not as the rank extravagances of gilded fools, is a yowling absurdity.

The Poor Man's Motor Cycle.

SO I had a kindly dream of some unborn genius who would do for motor cycles what Henry Ford has already done for motor cars, and sell usable solo machines at about £20 a time. It can be done, of course, and some day it will be done. If we don't do it, the Yanks will. If they go west before they get as far as that, the Japs will do it: and if the notion does not occur to the Japs when the yellow peril is top dog, Russia will do it when she is industrialised. Then the horny-handed son of toil will be able to invest, and to taste the joys of the road. He will have something better to do with his evenings than to trudge two miles to earth up his celery, or prop up a street corner, or sit on a hard, vertically-backed bench in the village pub until some sympathetic soul reads the visible thirst in his eyes, and passes over the pint pot. But this Ford motor cycle to come will not jump off with a four-speed gear. It will start its career very modestly with a two-speed. Which is why I wrote what I did. Partagas are all very well: but, if you cannot get one, a Gold Flake will do.



ABOUT AERO ENGINES

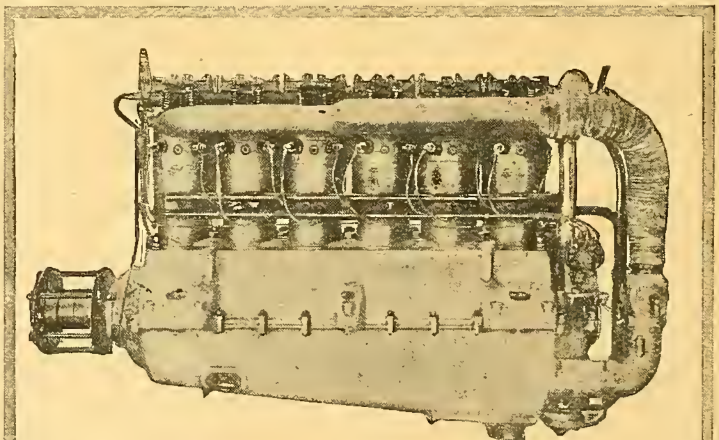


No. IV.—THE 260 h.p. GERMAN MERCÉDÈS AERO ENGINE.

Many of our readers are probably ignorant of the special features that distinguish aero engines from motor cycle and motor car engines. Samples of the leading types of aero engine are briefly described in this series of articles, the fourth instalment of which we print below.

THE latest type of German aero engine, described and illustrated herewith, possesses a very special interest, quite apart from the fact that two of these engines furnish the power unit of the raiding Gotha aeroplanes, or that we obtained these particulars from a Gotha which was shot down in battle. It represents the results of German study of aero engine design, and the German aero engine policy—a policy which is probably based on one of two blunders.

If German engineers concentrated on the six-cylinder vertical engine for aeroplanes because they fancied the war would last only a few months, and that the six-cylinder vertical was the type which they best understood and could most easily produce, they were technically right, and strategically wrong. If they fancied—as seems likely—that the six-cylinder vertical engine was intrinsically and permanently the best model for aero work, they were technically wrong. The engine under notice weighs 1,090 lb. approximately, without oil, fuel, or tanks, and develops 260 h.p. at its best flying speed. A rotary or radial engine can be built to develop equal h.p. power at half the weight; and the 5 cwt. saved by adopting a rival type of engine can be utilised for carrying additional weight, *e.g.*, in bombs, or for raising the climbing speed. Nor is weight the only handicap of the vertical six. It is abominably inaccessible, especially in an aeroplane, where it is lumbered up with gun gears, cowling, and other obstructions; you must take it out of the fuselage to perform any real work on it; and you will be lucky if you can remount it within twenty-four hours. By contrast, you can get the pistons out of a rotary or a radial in twenty minutes or so, without taking the engine out of the fuselage at all. Or, again, the six-cylinder vertical, with its tanks, occupies a very long stretch of the fuselage, as compared with the space required to house a shallow radial or rotary, and so makes for a machine which is slow on its controls, and cannot be developed into a first-class fighter. Or, again, if you prefer the V or Broad Arrow type of engine to the vertical, you can squeeze 520 h.p. or 780 h.p. into the space required by a six-cylinder 260 h.p.; or, alternatively, you can compress your 260 h.p. into a much shorter space by utilising a V eight-cylinder or a " triple four-cylinder." There is not a word to be said against the use of vertical sixes for certain types of plane, where sluggishness on the controls and lengthy engines do not matter, and where it pays to make sacrifices for the sake of a very substantial and durable engine.



The 260 h.p. Mercédès aeroplane engine. The bore of the cylinders is 160 mm. and the stroke 180 mm. Two inlet and two exhaust valves are arranged in the head of each cylinder, and are operated by an overhead camshaft running in a separate housing.

The Future?

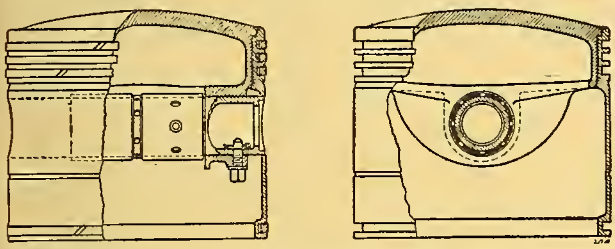
But through pinning their faith to one type of engine through 3½ years of war, the Germans now find themselves at the parting of the ways. For example, their best 1917 fighting scout, the Albatross, has this 260 h.p. Mercédès engine. It was notably outclassed by some of our 1917 scouts, and must be improved for this year. What sort of engine will their 1918 scout have? The Germans can hardly build bigger vertical sixes. Have they sufficient experience of the rotary, the radial, or the V to scrap their present policy and break out in a new type? Must they be content to build a lighter model of the 260 h.p. Mercédès? Their solution will be known very shortly. In the meantime they have made an obvious technical blunder.

About Aero Engines.—

They have mistaken for the *Ultima Thule* of aero engine design a type which is merely a motor car engine, figuring as a temporary makeshift during the transition from the road to the air.

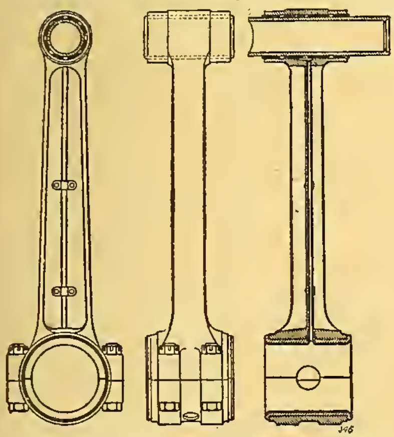
Mechanical Details.

When all this is said, we must admit that, as a vertical six, the big Mercédès is a very excellent job. It is built to last. The cylinder barrels are machined from steel forgings, and are screwed into machined steel heads.



Arrangement of piston, gudgeon pin and bush.

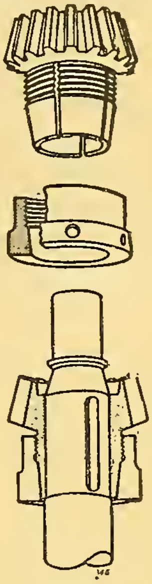
The water jackets are made of steel pressings in four sections, acetylene welded on to the cylinder barrels and heads. Domed steel piston heads are used, into which cast iron skirts are screwed and welded. (These pistons are about 4 lb. apiece heavier than they need be.) Each cylinder has four overhead valves, two inlets and two exhausts, of about 2½in. diameter apiece. The overhead camshaft is driven by bevel gearing off a vertical shaft at the rear of the engine. The crankshaft weighs 139½ lb., and is 64 mm. in diameter. One of the remarkable details of the engine is the floating gudgeon pin bush. In place of the usual fixed phosphor bronze bush, a loose steel sleeve "floats" between the gudgeon pin and the little end of the connecting rod; it is a perfect working fit in both of them, and is freely perforated with ¼in. holes, through which oil enters.



The distinctive feature of the connecting rod is the floating gudgeon pin bush. It is a running fit in the small end and also on the gudgeon pin.

The Oiling System.

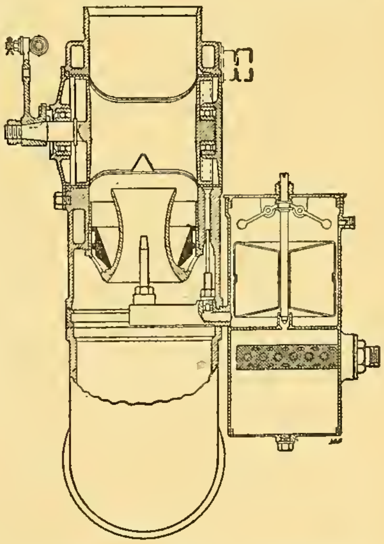
The lubricating system is rather complicated. After passing round the oiling circuit, the oil drains down into two sumps, located respectively below the front and rear of the crank case. A scavenging pump transfers the oil from the front sump to the rear sump; two sumps are needed because of the steep angles at which the engine is tilted in flight. The supply pump derives its oil from two sources; some of it is drainage oil from the rear sump, and some of it is fresh oil drawn from the tank by auxiliary pumps. When the oil in the rear sump exceeds a certain level, another pump returns the surplus to the tank. Thus a mixed stream of used and fresh oil is perpetually circulating. The oil channels through the engine are quite normal; as is usual on vertical aero engines, oil is pumped along the hollow crankshaft to the main and big end bearings, and up steel pipes (clipped to the connecting rods) to the gudgeon pin bushes. The pistons and cylinder walls are lubricated by splash with the oil which escapes at the edges of the crankshaft and connecting rod bearings. A separate pipe conducts lubricant to the inside of the hollow camshaft.



Details of the camshaft driving pinion.

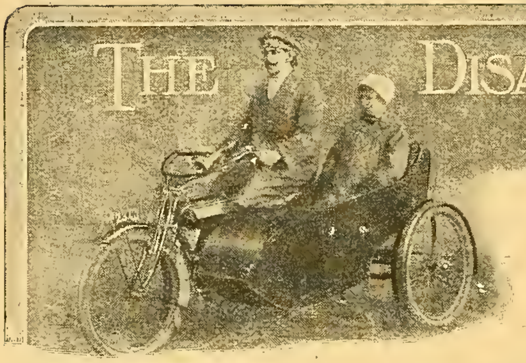
The valve springs are adjustable for strength; the upper ends of the valve stems are screw-threaded, and conical-based nuts are used in lieu of the cotters with which motor cyclists are familiar; the conical bases of these nuts fit into cones in the spring caps. The pilot can grease his water pump whilst in flight by means of a ratchet greaser with flexible wire control. The carburetter is quite commonplace, being of the two-jet type, with a suction valve for the admission of extra air. Its chief features are the mounting of the throttle barrel upon ball bearings, and the fact that the main air intake draws its air from the inside of the crank case.

The engine consumes rather over nineteen gallons of petrol per hour on full throttle, and about a gallon and a quarter of oil.



Sectional view of the carburetter. The main jet is situated in the centre of the intake inside the choke tube. The float chamber is of the ordinary balanced needle valve type.

Speaking at King's College, London, Sir William M. Ramsay recently said that the doctrine that a university was a nice place to send a young man to spend the most critical years of his life in doing as little as possible ought to be recognised as a danger to the State. Only through some great disaster could the nation have the lesson forced upon it. "So I ceased to be a lecturer on Latin," he added, amid laughter, "and began to lecture on aeroplanes." Such sentiments are commendable, and worthy of imitation.



THE DISABLED AND THE MOTOR CYCLE

Some Notes by a Humber Owner who began his Motoring while suffering under the Disability of having only One Leg.

It is unfortunate, but nevertheless true, that after the war we shall see many motor cyclists (who, before disaster overtook them, were dauntless and daring riders) adapting mounts for use with maimed limbs, and doubtless we shall continue to receive, in gradually increasing numbers, queries from lame men who have never ridden a motor cycle but who will be desirous of taking up the pastime. As matter pertaining to motor cycling for the maimed will be of interest to this unlucky section of enthusiasts, we publish the following notes and sensations of a lame man on first mounting a motor cycle. On March 29th last we comprehensively reviewed mounts well adapted for the use of the disabled.

IT was during 1911 that I first thought of taking up motor cycling. Five years previously I had lost my left leg, with the result that I have to hobble through life with an artificial fitment, which naturally is a serious handicap as regards getting about. One day early in the winter of the abovementioned year I was walking down the main street of my own town when I noticed a Humber motor cycle and sidecar standing outside a tradesman's shop. As I approached the outfit the owner emerged from the shop entrance, and, walking up to the machine, immediately started it by the application of a starting handle to the back wheel. The whole performance struck me as so simple that I returned home with my mind made up. It was the beginning of winter, so I postponed matters until the following spring, when I sent to the Humber Co. for their 1912 catalogue. On receipt of this I found that sundry improvements had been made since the manufacture of the model I had examined, so that I decided straight away to buy a 1912 3½ h.p. two-speed handle-starting Humber.

Ere I had given the order an advertisement appeared in *The Motor Cycle* of a 1912 two-speed Humber with light wicker sidecar, which had been about three hundred miles, and could be seen in my district. I immediately answered the advertisement, made an appointment, and finally had a trial run in the sidecar.

Altering the Gear Controls.

I knew nothing about motor cycles at the time, but had sense enough to realise that the engine pulled well, and that all working parts seemed to be in satisfactory order. The result was that I took the machine home with me that evening, and promptly discovered that the sidecar would have to be detached in order to allow the outfit to pass through my side entrance gate. Fortunately, the sidecar was of the quick-detachable variety, and it was only three minutes work to remove it from the machine. Now, having made my purchase I was faced with the problem of altering the gear controls to suit my purpose. Being handy with tools, I decided to do the work myself, and, as the machine is now rather old and somewhat out of date, I will not burden the reader with a detailed description of what was done. The foot controls, of course, had to be revised, and when I had finished they were arranged as follows: On the front of the right footboard were the low and high speed pedals, and near the back of the footboard was the back brake lever. I found it quite a simple matter to carry out these alterations, and, as the machine has now been in use for nearly six years, with the alterations still good, the adaptation may be regarded as a success.

The First Ride.

On the following day I took my first ride. It was a glorious day early in April, and having pushed the motor cycle and sidecar on to the road and screwed up all the couplings (which, to my pleasant surprise, was a less serious task than I had imagined), I was ready to start up the engine, which I found quite simple, owing largely to the half-compression device. In mounting the machine I found the most convenient way was to lift my artificial leg over the tank, and that the most comfortable position while mounted was afforded by having the leg quite straight and resting on the front arm of the sidecar. Thus, having arranged myself, I proceeded to engage the low gear, and the machine glided away as smoothly as the one I had observed in the thoroughfare.

I am afraid my abilities are not sufficient to attempt to describe the pleasure of that first run. I do not think I shall ever forget it. Imagine what it meant after being limited to walking about two miles an hour under the most trying circumstances to be able to fly along the road with neither effort nor discomfort. I remember laughing aloud to myself, feeling naturally overjoyed at the great discovery I had made, and it was not until I had covered fifteen miles that the thought occurred to me to return. Accordingly, I throttled down the engine and engaged the low gear. I then managed to turn within the width of the road without dismounting, and returned home by the same route, where I found my wife waiting anxiously at the gate, thinking something must have happened. Indeed, something had happened. I had learned in the last hour something

The Disabled and the Motor Cycle.—

that may conceivably add years to my life. The following day I was out again, this time accompanied by my wife in the sidecar, and since then we have travelled many thousands of miles together. I may say that the machine has given an absolute minimum of trouble, and I have never been held up on the road with anything more serious than a choked jet or a puncture. Although I am so seriously handicapped, I have experienced no insurmountable difficulty.

In conclusion, I would like to advise all those who have lost a limb, as I have done, to take up motor cycling as a means of getting about. It makes very little difference which leg is missing, as most makes of machines can be adapted to overcome one's infirmity. Those having lost a right leg would have to dismount, of course, to operate the kick starter, which in all cases must be depressed with the natural foot. I am sure that motor cycling would give pleasure and help to thousands of disabled men who might never have thought of indulging in such a pastime.

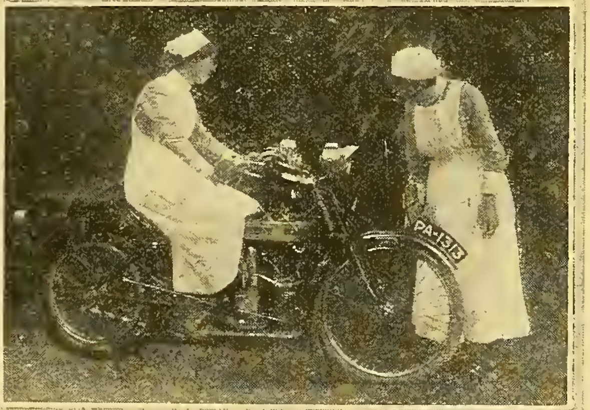
With the sidecar the outfit is quite rigid, and perfect safety can be enjoyed. I may add that I have found motor cycling a most health-inspiring recreation, and my wife and I have enjoyed very much better health since taking it up. F. W. PITHERS.

THE TOP GEAR MACHINE.

A Plea for a Higher Top Gear Ratio on Powerful Sidecar Machines.

AMERICAN car practice has produced a general striving among manufacturers in the direction of a top gear machine, which is a state of affairs I heartily regret. I have recently been riding a powerful twin fitted with a standard gear ratio of 5¼ to 1. This machine will thump over the summit of Edge Hill on its top gear, which, far from being a praiseworthy feat, seems to me merely to indicate that the top gear ratio is absurdly low for the normal conditions of riding, *i.e.*, during ninety per cent. of one's time one is called upon to tolerate high engine revs. and low road speed simply for the sake of climbing such hills as Edge on top!

Anyone who has watched the trend of design will have observed this general tendency in the direction of lower gear ratios for the last four or five years. In some cases it is frankly admitted by manufacturers that they have adopted low top gears simply on account of harsh transmission systems, it having been found that the short belt drive or all chain was appallingly snatchy if a fairly high gear ratio were used, whereas this defect was not so noticeable with a 5 or 5¼ to 1 ratio; but in the majority of cases the main aim has been a "top gear machine."



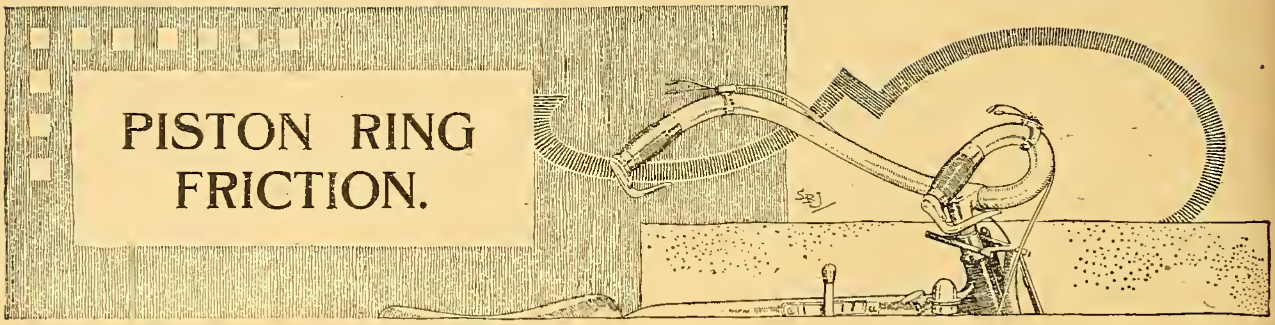
THE OFF-DUTY HOUR.
Nurses find interest in the doctor's Douglas.

A Comparison.

Now for vehicles of the Ford stamp, to be driven by all sorts and conditions of humanity, this top gear principle is excellent, but the average motor cyclist is a fairly intelligent individual who is anxious to get the best out of his machine, and is quite capable of using a gear box effectively. True, it is pleasant to be able to take all hills on top, but this can only be done at an immense sacrifice in comfort and in the way of speed on the level. The last big sidecar machine I owned was a Zenith Gradua, with a top gear ratio of about 3.5 to 1, and the way that machine floated over hill and dale was most delightful. In the interim I undertook a journalistic test of a chain-driven machine of the same power, having a 5 to 1 top and a big drop down to middle. Though the engine was a good one in every respect I was simply appalled by the clatter and revs if one attempted to open the throttle on the level. Though there was nothing to choose between the two engines, the Zenith had the chain-driven machine beaten in every way—comfort, speed, cool running, and petrol and oil consumption—owing solely to its high top gear. Most big sidecar machines are impossible as solo mounts chiefly on account of their gear ratios, and recently I found that a 2½ h.p. two-stroke lightweight was actually faster than a certain 5-6 h.p. twin solo! Even when riding in a mountainous district I have found a 4-1 top gear preferable to a 5-1 on a 7 h.p. sidecar twin.

What brought this point to my mind more forcibly than anything was a recent run accompanied by a 10 h.p. Singer light car. On the level I was easily left, but on hills my 4 h.p. sidecar was faster than the car—it being borne in mind that the weight h.p. ratio showed considerably in my favour. That the car was faster proved conclusively that my mount was too low geared for all-round efficiency.

Let us do away with this top gear notion; let us have four speed gears and use them. Every owner of a speedy light car knows that half the pleasure of driving is in "keeping up the revs" by artful handling of the change-speed lever. There is very little pleasure in driving a low-geared flabby-engined American car if one is used to a hot-stuff Britisher, and exactly the same applies to motor cycles. Most riders are willing to sacrifice the very occasional advantage of being able to climb a stiff gradient "on top" in order to gain the comfort and high speed a high gear ratio permits. CHINOOK.

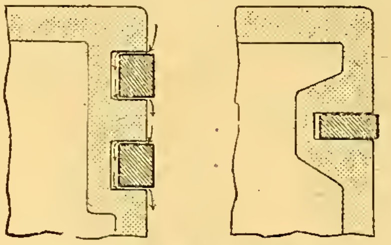


PISTON RING FRICTION.

SOME SUGGESTIONS IN CONNECTION WITH HIGH-SPEED ENGINES.

With the high-speed, highly-efficient, twin-cylinder engine of the future—for this type promises to be widely popular for solo use—piston ring friction must be taken seriously into account. With the ordinary touring engine, such as the popular 3½ h.p. single, designed to pull hard at comparatively low speeds, it does not matter a great deal whether two, three, or even four piston rings be used, or whether they be wide or narrow, but with the high-speed overhead valve engine we are up against an entirely different proposition. With this latter unit the rider is called upon to obtain his power at all times by means of "revs." Instead of plugging up hill with his engine turning over at, say, 1,500 r.p.m., he changes early and ascends with an engine speed of probably something well over 2,000 r.p.m. Also the efficiency engine runs comfortably on the level at a much higher rate of revolutions than the more ponderous variety, with the result that its all-round speed during the ordinary course of touring is probably 1,000 r.p.m. higher than the touring unit.

Now the piston losses due to the rings go up enormously with the speed, therefore the loss by friction (particularly oil friction) in an engine designed to run normally at high speeds is an infinitely more important matter than in the case of a low-speed engine. Indeed, it is a point of such great importance as to make good comparative petrol consumption impossible in the case of the high-speed engine if the piston and rings be badly designed.



The section on the left indicates how leakage past the rings most commonly occurs, while on the right is shown a type of ring which would not only tend to reduce this leakage, but to prevent friction.

An Undesirable Design of Ring.

The days of three and four piston rings are, fortunately, past—indeed, it is a moot point whether or not piston rings might be entirely dispensed with when the coefficient of expansion by heat in the cylinder and piston is the same. It is not generally known that a sleeve-valve car engine having no rings underwent a most searching test at the hands of its makers, and emerged with flying colours.

Supposing that we are to have steel cylinders and aluminium pistons, then we *cannot* dispense with rings, but what we can do is to abandon old ideas and pay more serious attention to the matter of friction, it being borne in mind that piston ring leakage goes down as the speed goes up, while friction goes up with the speed. Therefore in a high-speed engine it pays to sacrifice a little compression if by so doing we can considerably reduce friction. In the past we have used wide rings of shallow section, but these have proved imperfect in several respects. Every rider delights in finding his rings brightly burnished all the way round, but in point of fact this state of affairs does not in any way prove that no gas is escaping past the rings. The amount of gas which, at the worst, escapes through the film of oil between the ring and the cylinder is infinitesimal compared with the leakage that takes place *round the back of the ring*—this having been proved by practical research.

The wide, shallow ring is undesirable, then, because it presents a large surface to oil resistance, while its width is entirely unnecessary so far as its pressure retaining qualities are concerned. If it were half the width and double the depth it would do its work much better, for it would then obstruct leakage in the direction in which leakage is most probable, while still doing all that was necessary in the way of preventing leakage down the cylinder face. Moreover, the narrow and deep ring wears considerably better than the wide ring, and so does the slot carrying it, for the simple reason that, both the slot and the ring being deep, they are better able to resist the constant hammering effect of the reciprocating piston.

The Ringless Piston.

We have it, then, that the narrow and deep section ring is preferable to the wide and shallow variety in that, not only does it present a reduced friction surface (taking it that the tension of both rings is the same, oil friction will be reduced), but also it is better calculated to hold pressure. The objection to narrow rings is, I admit, their scraping effect on the cylinder, but this disadvantage could probably be ruled out by a judicious selection of metals.

What we shall probably come to in the high-speed engine for solo use is the employment of one top ring in a rather slack piston, with possibly a phosphor bronze oil scraping ring at the bottom of the piston. (We must not, of course, follow aero engine practice too closely, for here no pretence is made at efficiency, but it may be mentioned *en passant* that the piston

iston Ring Friction.—

learance on most aero engines is enormous.) Pos-ibly the single compression retaining ring will be of he obturator variety, but certainly it will not be of he old wide and shallow type.

Incidentally, it may be mentioned that if the narrow, leep section ring here advocated were employed in wo-strokes, we should experience less trouble with he top ring gumming (or welding) up—the gumming eing largely due to the escape of hot gas round the ack of the ring.

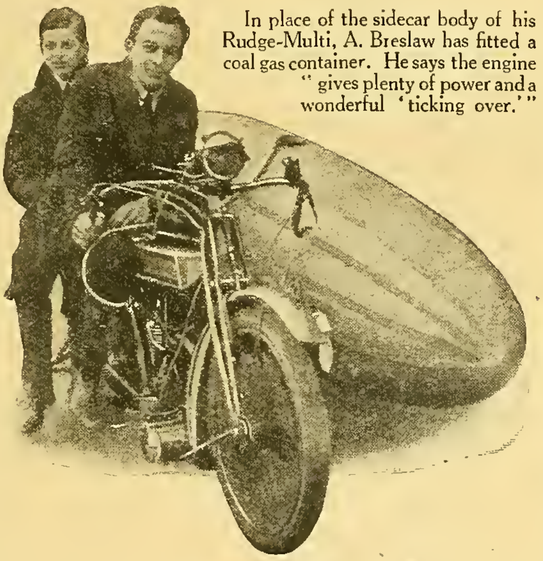
But, so long as we employ metals in two-strokes the eat expansion of which permits it, why not dispense with piston rings entirely? This really is what it comes to in practice, for the chief compression retainer is gummed in the groove during half its working career, with the result that it might as well be done away with altogether. It would not be difficult to design a piston which would retain compression reasonably well without rings (better, at any rate, than an ordinary piston with rings gummed up). The two-stroke is supposed to be the simplicity engine; why not make it truly simple, for riders of two-strokes do not demand vim, ginger, and m.p.h. so much as they demand an absolute no-trouble mount which can be ridden months on end without engine attention. CHINOOK.

COAL GAS IN PRACTICE.

A Continuation of our Notes founded on the Daily Use of Coal Gas.

WE stated in some previous Notes that, using coal gas as a fuel, we found that less lubricating oil was necessary than with petrol, owing to the lower explosion temperature. This indeed applies so long as scrupulous care is exercised in feeding the correct mixture to the engine; but it is an exceedingly easy matter, with the crude methods usually employed, to feed an incorrect mixture with no knowledge of the fact till the engine itself gives warning.

During the recent frosty nights our journeys home have been cut as short as possible by the simple expedient of turning on the gas tap and opening wide the throttle, and on several occasions after riding hard for about four miles we noticed a periodical choking and misfiring of the engine, which was put down to a kink in the gas pipe, and passed unheeded. Finally, however, it became so noticeable that we glanced down at the engine, and were somewhat disconcerted to see that the exhaust valve cap of the front cylinder, and indeed the whole valve pocket, was glowing a bright red.



In place of the sidecar body of his Rudge-Multi, A. Breslaw has fitted a coal gas container. He says the engine "gives plenty of power and a wonderful 'ticking over.'"

This same engine has been driven fully out on long journeys on petrol without indicating the least symptoms of overheating, and it is a curious fact that, even with coal gas as the fuel, overheating caused by an incorrect mixture would appear to occur only in frosty weather.

The effect of the atmosphere upon the engine with coal gas as the fuel is much more noticeable than with petrol. On and about sundown marvellously good results are generally obtained, the engine pulling almost as well as on petrol, while at other times top gear work, even on the level, is apt to be laborious, though the speed is fair.

NEW YEAR'S HONOURS.

The Order of the British Empire bestowed on Familiar Figures in the Motor Cycle World.

AMONG those who have received the various grades of the Order of the British Empire we notice the following, who are well-known in motor cycle circles: Mrs. Locke-King, vice-president North Surrey Division and Assistant County Director (Surrey) British Red Cross Society and the Order of St. John of Jerusalem, to be a Dame (D.B.E.) Mrs. Locke-King is the wife of the proprietor of the Brooklands Track, a keen motorist, and on many occasions an interested spectator of the various B.M.C.R.C. meetings. Mr. T. O. M. Sopwith, C.B.E., was an enthusiastic motor cyclist in his early youth, and is now the manufacturer of the well-known aeroplanes bearing his name. Mr. P. G. L. Webb, C.B.E., Deputy Controller of the Petrol Department of the Board of Trade; Mr. W. L. Baylay, O.B.E., manager of the Birmingham Small Arms Co., Ltd.; Major Charles Jarrott, O.B.E., Inspector of Mechanical Transport, R.F.C., the well-known motorist and president of the Motor Cycling Club; Mr. Alfred Bednell, O.B.E., general manager of the Cycle and Motor Cycle Manufacturers' and Traders' Union; Miss Henrietta Christabel Ellis, O.B.E., Commandant of the Motor Transport Section of the Women's Legion; Mr. H. W. Cole, M.B.E., Chief Clerk of the Petrol Controller's Department of the Board of Trade; Mr. A. F. Ilsley, M.B.E., Assistant Secretary of the Iron and Steel Committee, and secretary of the Engineering Committee, and a director of Phœnix Motors, Ltd.; Mr. Charles Temperley, M.B.E., Commandant and Transport Officer of the Metropolitan Special Constabulary.

Storing a Machine.

A great number of readers are now storing their machines for an indefinite period, and we are receiving numerous letters asking for hints as to their preservation. One point we would particularly recommend readers to make sure of is that the tyres are not rusted on the rims; if so, remove the tyres and shellac the rims, otherwise the tyres will soon rot through at the beading. It is best to hang the tyres separately over a well-padded support.

Preventing Cylinder Rust.

As regards the cylinders rusting, this should be carefully guarded against both internally and externally. The engine should be flooded with oil before leaving, run for a few minutes so as to distribute the oil over the combustion head, and finally left with the valves closed.

Greasing.

A convenient way of inducing the grease to enter all the crevices is to dissolve the grease used—say vaseline—in petrol, and apply with a soft bristle paint brush.

Lighting.

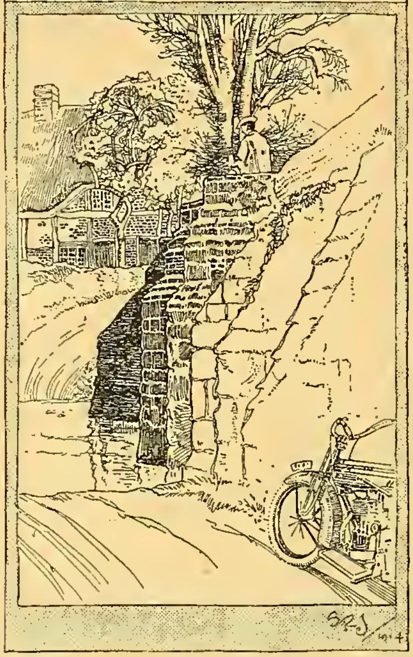
Numbers of letters continue to reach us suggesting means of overcoming the electric wiring problems advanced by "Chinook."

Motor Cyclist's Presence of Mind.

A motor cyclist, John Walker, licensed victualler, Old Kent Road, S.E., at Greenwich County Court last week, sued the owners of a car for damages through collision, negligent driving being claimed on the part of the driver—a boy of fourteen.

"One of the Oldest Motor Cyclists."

Plaintiff in evidence stated: "I saw it was impossible to avoid collision, so sat tight and received it. I was thrown into the road and the front of the machine telescoped. I said to the driver, 'What made you do such a silly thing?' He replied, 'It was all my fault, sir.' He was then taken away on the ambulance." Cross-examined, he stated that he was 'one of the oldest motor cyclists, and was not exceeding 12 m.p.h."



The Second-hand Market.

It is a surprising fact to us that the market for second-hand machines still remains lively. A member of our staff, on advertising a luxurious outfit at a price exceeding 100 guineas, promptly received a number of enquiries, mainly from doctors and mill owners.

More Humour from Queries.

Certainly the editorial life is not all beer and skittles, but we do have our little jokes sometimes. As we have said on more than one occasion, the most frequent source of laughter in the frigid gloom of our sanctum—where the temperature seldom exceeds zero in winter, and just as consistently keeps above blood heat in the summer—is the delightfully unconscious humour shown by many of our correspondents. One of our letters recently contained a P.S. to the effect that we need not trouble to type the answer, and that a piece of paper was enclosed for us to write on! And sure enough the querist was as good as his word, and had enclosed a piece of paper for us "to write on," as well as the stamped addressed envelope for reply!

Queries—Real or Faked?

And on top of a thing like this we meet a friend who calmly says he was always under the impression that the queries we publish all emanate from the office! In other words, he thought we had nothing better to do than make enquiries for the sake of answering them!

Special Features.

PISTON RING FRICTION.

THE DISABLED AND THE MOTOR CYCLE

THE DEVELOPMENT OF THE PASSENGER MOTOR CYCLE.

Some Schoolboy Howlers.

We think the youngster must have been a motor cyclist who, when asked to explain the force of gravity, said that it meant a limit of ten miles.

Another bright youth said, in his examination paper, that a vacuum was a place where the Pope resided.

Commandeering Laid-up Motors.

A common topic of discussion in motor car circles at the present time is, "Why do not the Government take over the thousands of cars that are now lying idle in their garages, and so save money, material, and labour from the production of new cars?" If the Government should wake up to the possibilities of this suggestion, could not the scheme also apply to some of the motor cycles now sharing the same fate as their larger sisters?

For the Italian Army.

We are informed that a number of Matchless motor cycles are under construction to the order of the Italian Government. The machines have been tested under the recent severe weather conditions, over ice and snow-bound gradients on the Kent hills, with ten degrees of frost. One machine was tested with three up.

"The Motor Industry."

Mr. Horace Wyatt, an old contributor to *The Motor Cycle*, who has made for himself a conspicuous place in the motor world, has published, through Sir Isaac Pitman and Sons, Ltd., a new and important work, "The Motor Industry." This is the latest addition to these publishers' "Common Commodities and Industries" series, which now comprises some five-and-twenty volumes. "The Motor Industry" begins by tracing the history and developments of the motor, and proceeds to illustrate the theme with descriptions and pictures of every type of machine from the practical traction engine at the one end of the scale to the most luxurious car at the other. Particular stress is laid upon the important part which the motor is bound to play in the future developments of trade and, in particular, of agriculture. Suggestions also are offered towards the advancement of this industry in Great Britain. The time is coming, indeed has come, when every nerve must be strained by the people of this country to win a foremost place in the competition of the nations.

al Gas as a Fuel.

We are informed that the Order affect- g the control of the use of coal gas will ot come into operation until the 1st of ebruary.

he New Year's Honours.

In the list of New Year's honours we ote the names of Mr. P. G. L. Webb, eputy Controller, Petrol Controller's epartment, and Mr. H. W. Cole, Chief lerk of the Department, who have re- eived the Order of the British Empire.

otorists' Protection Association.

An association having for its object he protection of the private motorist as recently been suggested in London. he secretary *pro tem.* is Mr. H. E. anderson, Sussex House, 42, Howard oad, South Norwood, London, S.E.25, nd any reader interested in the scheme s advised to put himself into communica- ion with Mr. Sanderson.

till More Aeroplanes Wanted.

Sir Douglas Haig, in reviewing last ear's fighting, said : "The enemy shows o sign of relaxing his endeavours in this epartment of war. While acknowledg- ng, therefore, most fully the great effort hat has been made to meet the ever- ncreasing demands of this most impor- ant service, I feel it my duty to point ut once more that the position which as been won by the skill, courage, and evotion of our pilots can only be main- ained by a liberal supply of the most fficient machines."

or the Disabled.

The following donations have already een received in reference to the appeal ssued by the Central Committee for the mployment of Discharged Soldiers and ailors connected with the motor ndustry:

The B.S.A. Co., Ltd.	£200	0	0
The Daimler Co., Ltd.	200	0	0
The National Society of Chauffeurs' "Sixpenny Fund"	150	0	0

	£585	3	0

ost-war Output.

In last week's issue of *The Autocar* 'Runabout" has some very interesting emarks to make on the post-war output f cars, and of light cars in particular. As the conditions in both industries are much the same, it may be taken that the substance of his remarks applies equally to motor cycles as to cars. It is "Runabout's" opinion—and "Runabout" is a man well able to judge, and one not likely to jump at reckless conclusions—that for some time after the war the demand for motors will be enormously ahead of the supplies, and consequently it will be some time before any noteworthy fall in the price of new cars becomes evident. "Runabout" has no hesitation in advising all who are likely to want cars after the war to place themselves on the waiting list of some firm, so that they may be reasonably assured of having their requirements met in a reasonable time.

The Waiting Lists.

It is common knowledge that several of the more prominent car manufacturers have their total output booked up for some two or three years after the declaration of peace.

The Ramsey Oil Find.

Many of our readers will have seen that the Ramsey oil find has been explained away by being attributed to leakage from a tank. It has been suggested in some quarters that this explanation may be due to a desire on the part of the Government to prevent the discovery of any oil in the country. We offer no comment on this suggestion, but it seems rather at variance with the recent Government decision to prospect for oil in these islands on a large scale.

A Draw for War Bonds.

Taking advantage of the custom of Christmas "draws" which is so prevalent in most large works, the Dunlop Rubber Co. gave their employees an opportunity to participate in a draw for War Bonds instead of the usual prizes.

The scheme was put through in a week from start to finish, and £514 was raised in shilling tickets. The first prize was forty per cent. of the total subscriptions, and other prizes worked down the scale to complete the total amount subscribed.

A Motoring School for Prisoners of War.

We recently mentioned the formation at Vevey of a motoring school for British interned prisoners of war invalided from Germany to Switzerland. This school is under the control of Lt. Wallis, late of the staff of *The Autocar*. Subscriptions to enable Lt. Wallis to carry on his excellent work are needed, and any reader who is willing to assist this most praiseworthy scheme should send his subscription to the Editor of *The Autocar*, Hertford Street, Coventry. The work and progress of the school are periodically described in *The Autocar*, and an interesting page is devoted to the school in last week's issue.

The Consolidated Petrol Order.

Any reader who wishes to have the full terms of the new Petrol Order for purposes of reference will find them in *The Autocar* of January 12th.

The R.A.C. of South Africa.

The R.A C. of South Africa, like the home body, is doing a considerable amount of work in the transportation of wounded soldiers, both with cars and motor cycles.

A Striking Car.

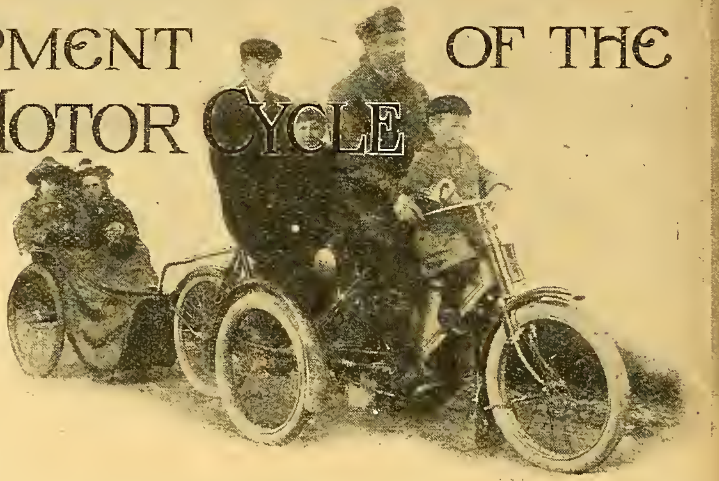
One of the most original and striking cars that has ever been designed is the Fergus. This car originated in Belfast, and was on view in Coventry in 1914, but, owing to the war, its manufacture became impossible. Mr. Ferguson, the designer, took his patents to America, and it is interesting to know that this car is now being launched on the American market. The car bristles with novel features, the most striking of all being that the car requires practically no lubrication for months on end. If this object can be achieved in a car, why should it not be equally attainable in the case of a motor cycle?

Testing Military Motor Cycles.

The illustration on this page is of Triumph machines undergoing official test prior to their final acceptance for the army. Each machine is ridden by an officer, chiefly to ensure that it is developing its full power, though sometimes a cross-country jaunt, including hillocks and ditches, is indulged in. On the right are the two official testers, while on the left a Triumph tester is in the act of returning to the works with an accepted machine. He then returns with a fresh mount, each tester bringing three machines for examination.

Triumph machines being tested by Government officials (see paragraph).

THE DEVELOPMENT OF THE PASSENGER MOTOR CYCLE



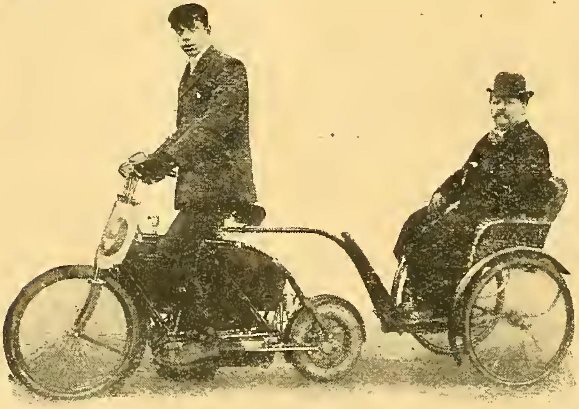
So far as motor cycle practice is concerned, the tricycle, to which was attached a trailer, was the first method of carrying an additional passenger, The illustration shows a tricycle with an extra wheel at the rear as well as the trailer. Considering the power of the engine, presumably about 3 h.p., the load is considerable.

THE GENESIS OF THE SIDECAR.

IN the early days, when practically all motor cars struggled along under power derived from single-cylinder engines, the motor cycle was in such a crude state of development as to be almost truthfully described as non-existent. There were, however, attempts at making light passenger-carrying vehicles running on four wheels, and following much that afterwards developed into motor cycle practice.

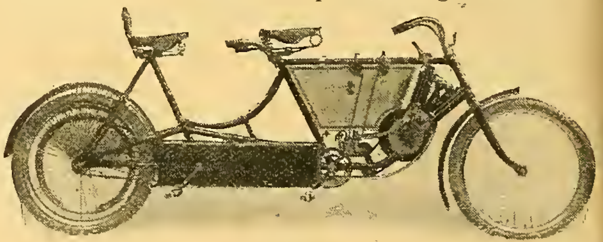
With the exception of the old Bollée and Century tandems, indications point to the De Dion tricycle as one of the earliest attempts at passenger carrying. To the best of our recollection, the trailer was introduced in Paris as an adjunct to the De Dion tricycle. The trailer was followed by a forecarriage attachment which was nothing more or less than the fitting of a trailer body in front of the tricycle, removing the front wheel, adding a pair of steering wheels, and connecting the front fork end of the tricycle to the steering arms of the forecarriage wheels. This type was followed by an *unconvertible* four-wheeler known as a quadricycle. These four-wheelers first appeared in this country at the Stanley Show of 1899, being exhibited by the Ariel and Enfield Companies. These models competed in the famous R.A.C. trials of 1900.

A few half-hearted attempts were made to market a tandem lady-back motor cycle, and some of these machines were to be seen on the roads as late as 1911. They were, however, never an unqualified success, one of the most obvious disadvantages being the liability to serious sideslip.



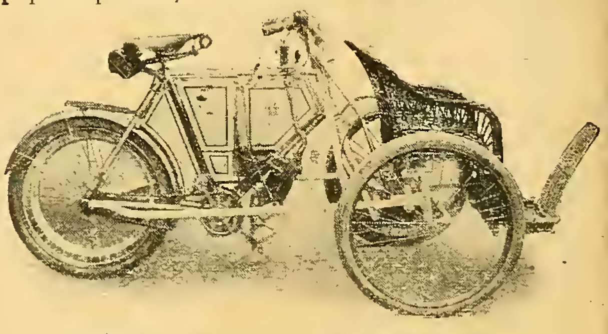
The motor cycle and trailer succeeded the tricycle and trailer in natural sequence, and had considerable popularity in 1902 and onwards. The photograph shows the Holden motor cycle, which had direct drive to the rear wheel.

In 1903 a new type of passenger machine made its appearance in the shape of the Singer and Phœnix tricars, which were soon followed by the productions of the Rex and Humber Companies along similar lines.



The tandem motor cycle. This type of passenger-carrying vehicle had but very short vogue. The position of the Clement-Garrard engine and the small angle at which the cylinders are set are noticeable features.

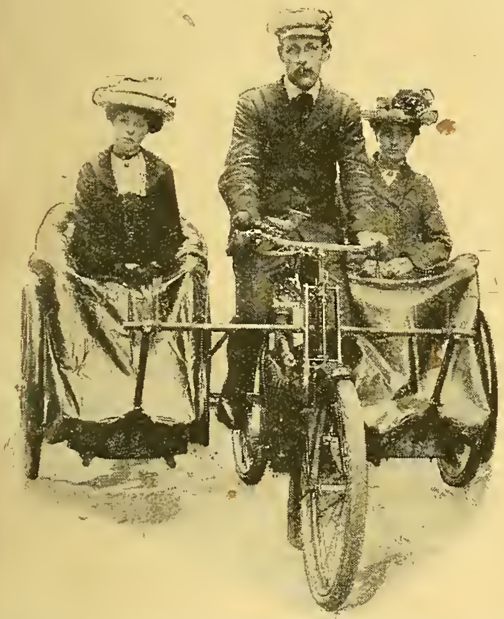
These tricars generally consisted of a motor cycle from the handle-bars rearwards, with the single front wheel replaced by a pair, between which the passengers' seat was arranged. The illustration given is of the Phœnix Trimo, which was, of course, a deservedly popular pioneer, and did invaluable work.



The Phœnix Trimo, a type of tricar in evidence in 1902-3.
The power of the engine is 3¼ h.p.

he Development of the Passenger Motor Cycle.—

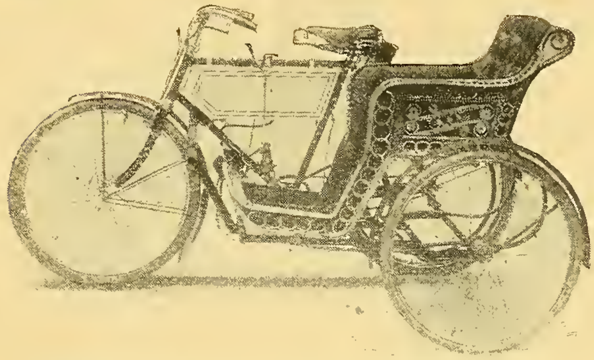
In the same year (1903) the first trailers attached o cycles were seen on the road. The main point in ll these arrangements was simple and easy detachbility, so that the machine could be used either for assenger-carrying or for solo use without the expendiure of much labour in the conversion. The removing f the forecar obviously left much to be desired, and n 1903 the makers of the Ariel motor cycle marketed he "Liberty Sociable Attachment," which, so far s we are aware, was the first sidecar to be put upon he market in any quantity. It was made under icence by the firm now known as Components, Ltd., aving been invented by the brothers Graham some ine months previously. It is of considerable interest o note that Messrs. Components, Ltd., allowed the atents to lapse, as they thought the future of the idecar to be so unpromising! Had they preserved their rights they would have drawn a royalty on every sidecar made since! Mr. Montgomery, the well-known sidecar manufacturer, tells how he vainly tried to convince Mr. Sangster, of the Components Co., that the sidecar *had* a future.



A type of passenger machine which, for obvious reasons, never "caught on," although now and again, even in these enlightened days, letters are received asking why a sidecar should not be placed each side of the motor cycle.

In *The Motor Cycle* of this year (1903) a most interesting article appeared, reviewing the experiences of "trailering" as it was called, and it gave several hints and tips as to what machines would be most suitable and what should be avoided for the job of carrying a passenger; 2 h.p. was recommended as satisfactory and 2¾ h.p. as ample. If, however, a two-speed gear were fitted, 2 h.p. would be adequate for any serious touring!

The gap between these ideas and those of the present day is too obvious to need elaboration. Further advice given was always to start downhill, while the writer of the article in question stated quite barefacedly that the question of sociability was not at all important, as the machine took so much looking after.



The Ariel sidecars were among the first used on the road. The engine is a 2 h.p. Minerva "Spray."

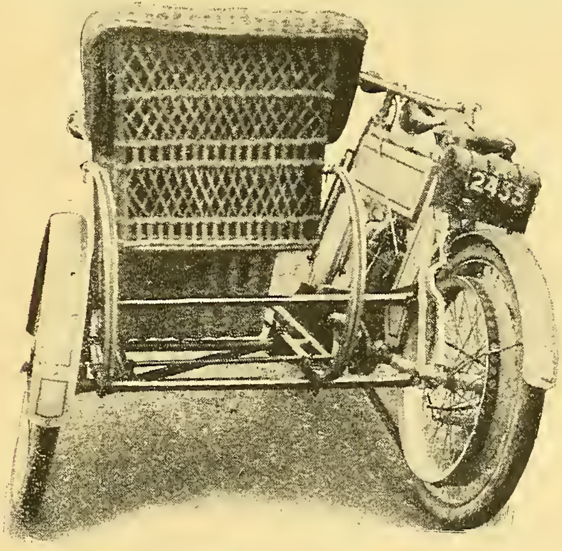
The passenger, who also gave her experiences, recommended to other passengers that they should always take a book, so that in case of a breakdown they would have something to pass the time away while the machine was being repaired.

Other Sidecars.

The coming of the Liberty sociable attachment apparently set others thinking, but which form of passenger attachment would ultimately win the day was as yet far from being a decided question, and in 1903 Messrs. Mills-Fulford introduced a new sidecar which could be converted into a trailer at will. Further evidence of the uncertainty obtaining as to which machine would ultimately come out on top is afforded in *The Motor Cycle* so late as 1905, where there is a statement to the effect that the tricar had not yet completely ousted the sidecar!

Rear Cars.

Many of our readers will doubtless remember that within the last few months particulars of an American contrivance called the Cygnet Rear Car, and an English arrangement on similar lines called the Backcar, have been published in *The Motor Cycle*. The accompanying illustration shows two sidecars coupled



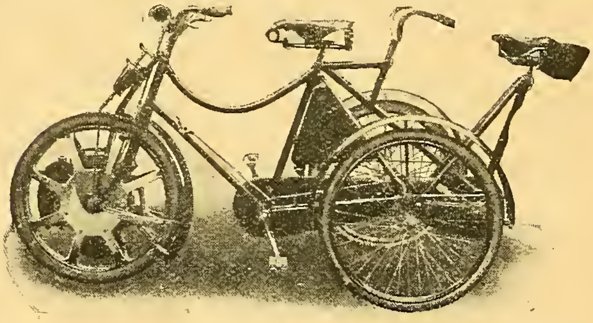
The flexible type of sidecar had many admirers at the time of its inception. Its peculiarity was that the body remained vertical even though the cycle might be leaning over. The illustration gives a good idea of the movement.

The Development of the Passenger Motor Cycle.—

to the motor cycle on either side in the usual way in front, and coupled to it and *via* the motor cycle frame to each other behind, an arrangement that rather suggests the rear car attachment. Several ideas were put on the market on similar lines in these early days, but this is the earliest, and to the best of our knowledge the closest, forerunner of the new rear car arrangement. But in the same year the Kyma sociable made its appearance. This machine is quite unique, but as the illustration shows practically all that is of interest, it may be passed over with a remark or two emphasising a few salient features. For instance, a popular subject for discussion in cycle car circles when cycle cars were making a fresh struggle for existence in 1912 and 1913 was the question of transmission, and several successful machines, notably the G.N., were put on the road, provided with chain drive from engine to countershaft, and thence belts to the rear wheels. It will be seen that the Kyma three-wheeler has this arrangement. The radiator fitted is no clumsier than were most radiators at the time.

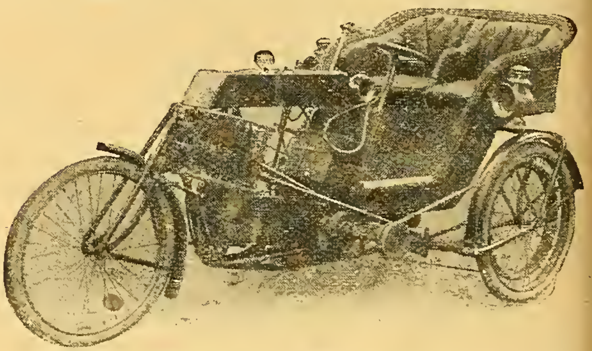
The Flexible Sidecar.

About this time a fresh type of sidecar made its appearance—in the shape of the flexible. As this is now practically extinct, some new readers, perhaps, may be surprised to hear that it was specially arranged so that the cycle could lean at an angle when taking corners, just as if it were ridden solo, while the body of the sidecar remained upright. Although such a device as this was on the market as early as 1903, the illustration is the earliest available, and is taken from *The Motor Cycle* of June, 1905. The flexible sidecar died a natural death, but there is no doubt that it had many advantages in riding. Its main drawbacks were, of course, that the combination was just as liable to skid as was a solo machine, and also when standing the motor cycle had to be raised on to the stand, just as if no sidecar were attached.



The Singer "trike" had the power unit in the front wheel. Accommodation was provided for the passengers by fitting a second saddle at the rear, together with a pair of handle-bars.

Even so early as 1904 the tradesman's sidecarrier was on the road, although, of course, it is doubtful if this idea met with any considerable measure of success much earlier than 1912 or 1913. The tradesman's sidecarrier has gained enormously in popularity during the war, but it will surprise many of its users to hear that a specially constructed sidecar body for the carriage of goods was on the market so long as fourteen years ago.



The Kyma sociable, a curious passenger vehicle, seen on the road in 1903. It will be apparent that several modern features are incorporated.

Another ingenious device that attained a measure of popularity in these years of experiment and trial was a coupling for a push cycle and motor cycle. This consisted of several metal strips for the purpose of coupling an ordinary push cycle to a motor cycle, so that when together the pair made a compact four-wheeled vehicle. The passenger on the push cycle carried his or her hands on the handle-bar, but did not make any attempt at steering, which was left to the motor cycle rider. Several of these coupling devices were put on the market, the first probably being that by the makers of the first sidecar, and it went under the name of the Ariel coupling.

(To be concluded.)

SOME INTERESTING LEGAL CASES.

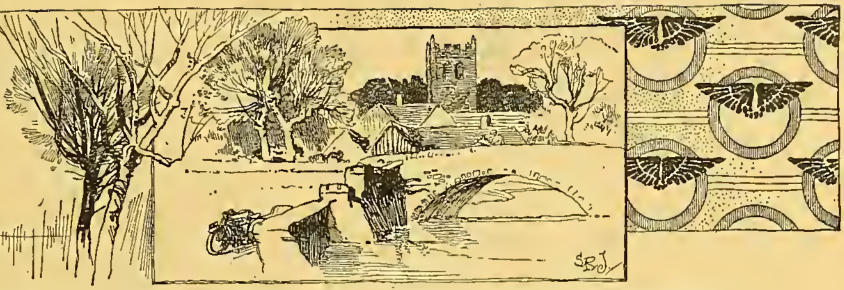
A SHORT time ago there appeared in *The Motor Cycle* an account of the work of the Auto Cycle Union during the war, and reference was made to cases in which the A.C.U. had been successful in helping members.

The following details of cases in which the A.C.U. was successful in defending several motor cyclists prosecuted under the new Order were furnished to us through the courtesy of Mr. Noel Berridge, of the Royal Automobile Club Legal Department.

At Sale, Cheshire, a motor cyclist was in the habit of riding his machine on business from his works, where he was employed as an electrical engineer, and also occasionally from home to the works. There was a tramway service, but he sometimes used the motor cycle if the trams were not running. On the particular occasion on which he was stopped he had taken the machine home for repairs, and was bringing it back to the works for use in the course of his business later on in the day. The case was dismissed.

In Birmingham, a soldier who had been discharged from the Army through ill-health caused by wounds was working at the factory of Messrs. Vickers, Aston. His ill-health contracted while in the Army caused him to suffer severely from heart-trouble. He was situated one and a half miles from a motor omnibus starting place, and found that waiting in a queue for a place in a vehicle aggravated his heart trouble, which also prevented him from using a pedal cycle. As the case rested upon the point as to whether he was justified in using motor spirit when an omnibus service was reasonably convenient the case was dismissed.

A TEARFUL GOOD-BYE.



How the Dust of the Highway was Responsible for Great Misunderstandings.

LOOKING back I remember a lighthearted band of about one hundred despatch riders starting for the Front. After weary months of training they raced off like hounds let loose from the leash. Equipped with brand new machines, they flashed through the villages, while folks came out to see and cheer them on their way. It was in the earlier stages of the war, when khaki-coated men on motor cycles were not so common as now. Like thorough sportsmen, they were eager to get out, so eager that, with heads bent low on the handle-bars and throttles fully open, one would have thought that the fate of our arms depended on their immediate assistance.

It was a glorious summer day. Clouds of dust, wafted by a gentle breeze, refused to settle, as if annoyed by the constant disturbance of the whirring machines.

At the first stop all was well. Hearts were too full and brains too excited to be troubled by such a trifling inconvenience as a bit of dust; but, at the second stop, amid a good deal of nose-blowing, complaints were made of the nuisance, and several with inflamed eyelids seemed rapidly to be developing violent colds in the head. But what is dust to men about to face shells, gas, and bullets?

At the third stop the growl was distinct and ominous. Men without goggles blamed their carelessness, while men provided with them found fault with their quality. This dust was not the ordinary sort. It not only penetrated through goggles of the most approved design, but was impregnated with tar, or creosote, or some vile preparation used in repairing roads. The irritation when it got into the eyes was considerable, and for a time the sufferer was partially blinded. A very different looking lot of men from the merry band who started were these when they arrived at the port of embarkation. Tear-streaming and swollen-eyed they might have just come from the inspection of a pickled onion factory.

A Sympathetic Crowd.

A curious, yet sympathetic, crowd assembled round the weeping warriors. Kind ladies remarked, "Poor dears, how sad for them to have to leave their wives and children!" Men bit their lips and choked back their tears, but the temporary check only served to double the violence of the outburst.

The juvenile portion of the crowd would insist that they were returned wounded heroes still in the throes of agony. An urchin asked one more tearful than the rest if he had been gassed. The reply sent the youth away reflecting whether he had heard aright, or that the flood of language was attributable to the same cause as the other overflow.

Long queues of sufferers for eyewash treatment formed outside the local chemist shops. It was a regular sick parade, and the youngsters, now fully convinced as to the real status of the soldiers, asked for French souvenirs. The treatment only gave temporary relief, and the scorching sun was intolerable. All sought any available shade that could be had, and the very fact of men shading their faces with their hands must have given the impression that they were trying to hide their weakness from observation. The sergeant-major, shedding bitter tears, announced that the men would receive pay before embarking. Never before had he shown publicly how affecting it is to have to call a pay parade, while the officer who sat at the pay table appeared quite sorry to part with so much money, as he paid with one hand and applied his handkerchief with the other.

The Strength of Circumstantial Evidence.

Old soldiers attempted to show solicitude for the younger men. One old veteran went up to an apparently heartbroken youth, and said, "Cheer up, son; don't take it too much to heart." "I ain't crying for that," indignantly returned the weeping one. "Never mind," added the other doubtfully, "you'll soon get over it." It was useless denying it, circumstantial evidence was too strong. Sailors remarked, jocularly, that the tide would not come in any quicker for the addition of a few extra drops of salt water. One man was so exasperated that he insinuated that the whole affair was a stunt of the authorities. He contended that they had been put purposely over a specially prepared course as an experimental test, and vowed vengeance on the perpetrators of the trick.

But the most humiliating scene occurred when the hospital ship arrived. The wounded Tommies thronged to her sides and cheered madly as they moored alongside the quay, but all the response they got was a choking sob or a feeble wave of a handkerchief, which could not be spared for long from its more urgent duties of tear mopping. Our broken and melancholy appearances must, indeed, have damped their spirits, for an atmosphere of oppression seemed to have settled on the whole vicinity.

At last aboard ship they left dock to the strains of—I believe the band played that pathetic melody, "Oh, dry those tears." I am not quite sure, because I was attending to my own troubles with a bottle of diluted boracic solution.

It was altogether the most tearful party I have ever witnessed, but the cool night and sea breeze soon eased the suffering, and next day a merry band was speeding along the long, straight, tree-lined roads of France.

L. J. WILLIAMS, SGT. R.E.

ADVENTURES WITH and WITHOUT LEAVE

How Fate oft dogs the Footsteps of the Over Ambitious.

THERE is a special animosity of fate seemingly reserved for those who desire to crowd the maximum amount of effort into the minimum time, and generally one stroke of ill-luck never comes without a second in its train—the reserves of misfortune's artillery, as it were, brought up in case the victim should survive the first shock.

The Imp of Perversity has nowhere shown himself so assiduously attentive as towards the men of a certain M.T. repair depot situated "at home," who, before the banning of "pleasure" motoring, were wont to snatch a few surreptitious hours with their families.

The working hours at this place permit the freedom of the staff from tea-time on Saturday until Sunday night, thus giving about thirty hours' time made precious by the fact that it is free from all military duties and obligations unless one happens to be detailed for "guard" or "fire picket," which occurs more often than not.

One could not fail to admire the pluck of those riders who accomplished runs of as much as 150 miles on oft-times disreputable old crocks in order to snatch a few hours with their people and then did the return journey against the clock, with "umpteen" days "C.B." overhanging as a penalty for unreliability of the machine—incidents which illustrate to what length a soldier will go in order to visit his people.

Such a fate befell two enthusiasts who invested a small sum in an antique one-cylinder car, with which, after much "tuning," they set out for their home, 110 miles away, one Saturday evening.

In the first mile the magneto chain broke, and after this was repaired the outfit did not exactly prove to be a Grand Prix racer; lamp troubles and minor defects resulted in a low average speed, whilst the engine gradually lost power as the miles went by owing to the spindle of the circulation pump having seized and broken, with the result that the water had mostly boiled away. They reached their destination at 2 p.m. on Sunday after a journey at the average speed of 7 m.p.h.!

The unfortunate sequel to the outing was the missing of the return train, and on arrival at their depot, three hours after *reveille*, the wayfarers were awarded fourteen days' C.B. by an unsympathetic C.O.

A curious chain of accidents happened to one machine, the joint property of three men. The first rider tried conclusions with a motor 'bus, and, although he was thrown clear, the 'bus passed over the carrier and rear wheel.

The next time the machine was on the road, the second of the three part-owners was travelling along at a good bat when he ran into a low mist, left the road, and, after a few lurid plunges in the grass, came up hard against a telegraph pole. He was able to continue an eighty-mile journey after a little rest to recover his sense of whereabouts.

The third man had the machine on the first week-end after the resetting of the clocks from "summer-time," and was hastening homewards with only the small light permissible in military areas, when, seeing what he imagined to be a dark patch of unrolled metal in his path, he steered for the narrowest part of it, and at once found himself describing a tremendous parabola through the air; he landed head first, but the stiff peak of his cap saved him from being knocked senseless.

It was some time before he recovered sufficiently to pick up his machine and discover that the object which had thrown him was a horse, sadly mangled, lying dead in the road.

A Thoughtless Omission.

The beat of an engine coming along the road at this moment caused our friend to gather his dazed wits and endeavour to stop the newcomer by violently rocking his handle-bars, on which the head lamp was still burning. The warning was just in time, and the rider pulled up within inches of the carcase; simultaneously, the lights of a car appeared in the opposite direction, and this was also stopped in safety.

It is awful to contemplate the possible consequences had the first motor cyclist remained unconscious and the second and also the car had all got mixed up together.

The arrival of a constable elucidated the mystery. The horse, straying on the road, had been run down by a motorist, who foolishly left it without any light or warning in order that he might advise the police of the accident, with the above consequences during his absence.

Adventures—with and without Leave.—

After an hour's rest and copious "injections" of stimulant, our friend was able to complete his journey of ninety miles, despite the fact that his left wrist was so badly sprained as to be useless.

One would imagine these misfortunes enough for one outing, but, on the return journey, the timing-shaft broke! A two-mile push to the nearest village, a five-mile walk to a main line station, and a skirmish with the "red-caps" brought the victim of misfortune back to barracks none the happier for his outing.

The above accumulation of trouble is almost equalled by the adventures of Private X——, who started one night on a brand new two-stroke for his home, some seventy miles away; he carried a spare tin of petrol, and in fifty miles this chafed through and allowed a steady drip on to the belt, thus distributing the spirit over the machine and rider until the rear lamp caught fire and the whole was rapidly ablaze!

Saving himself by rolling in the roadside grass, the unlucky X——, after watching his machine burn out, disgustedly walked to the next village, hired a pedal-cycle, and almost reached home, when, at the foot of a hill, he skidded, struck a wall, and hopelessly buckled the cycle forks, and was thus compelled to complete the distance on foot.

He was not "out of the wood," however, for, before departing from the bosom of his family, his adventurous offspring succeeded in pitching a stone through a neighbour's plate-glass window.

A Story with a Moral.

The concluding incident of this chapter of accidents occurred to the writer during a four-days' leave, and for convenience it may be told in the first person.

I was on a visit to a relative in an out-of-the-way Yorkshire village, and owing to the rain had been greatly troubled by belt slip, and so, for the return journey of thirty miles odd, decided to raise the gear. In endeavouring to loosen the pulley locknut with a hammer and chisel (foolishly over-confident of my old trusty Triumph I had started without any tools), I found that fifteen months of neglect had caused the part to become immovably rusted.

A hasty and injudicious blow and calamity! I had broken the pulley boss. Removing the pulley I set out on a two miles tramp, over fields sodden with incessant rain, to the nearest place where I could obtain a drill, and I there fixed the loose flange by means of three studs.

The repair was satisfactory, and, darkness approaching and having no lamps, I made good speed over the first six miles, when the belt broke; a rather short spare on the machine was only forced on to the pulleys with difficulty, and the strain proved too great, for after about fifty yards the pulley burst at the drilled holes into which the studs were fitted, and so I was completely stranded five miles from a station and twenty-four from home!

Rain, wind, and hills made it a hard push to the railway, only to learn that there was no train that night, but at another station, five miles further along, I might catch the last.

A Strenuous Journey.

The next five miles seemed interminable, and I had to struggle against the inclination to lie down at the roadside and sleep. The rain, accompanied by lightning, was incessant, and at the end of four hours I was so exhausted that the machine overbalanced and for some time I was unable to pick it up.

I was still staggering on in little stages when a motor car drew up (the only vehicle I saw in the whole distance) and the driver offered me assistance; being just returned from his works he suggested our going there and setting one of the night shift men to make what was required, but when I pointed out the impossibility of making a pulley, off-hand, as it were, he insisted on my abandoning the idea of pushing the remaining nine miles. Taking me to his house, near by, I was able to telephone home, and having fed me and dried my soaked clothing this good Samaritan lent me a pedal cycle and took charge of my old 'bus, assuring me of its safe arrival on the morrow by one of his own lorries.

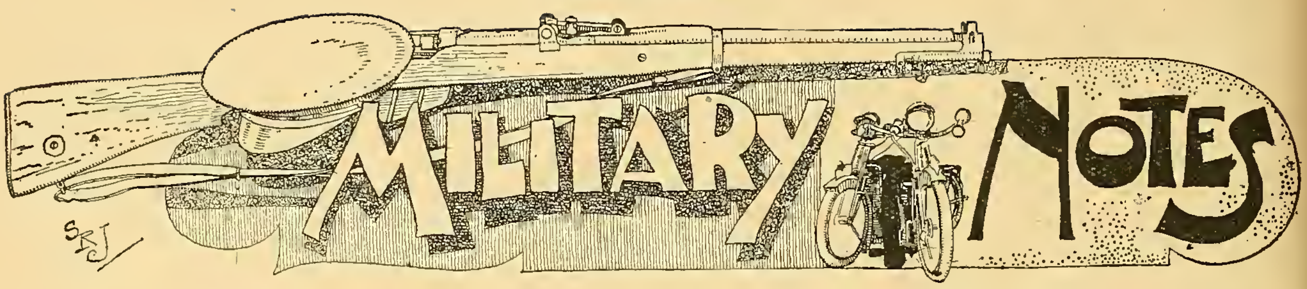
My first attempt with the pedal-cycle was a failure, for I was so tired that I promptly fell off, but I reached home in the early morning, having walked four miles, motored six, pushed the machine sixteen, and pedalled eight!

Thanks to the assistance of Mr. W——, the kind-souled munition maker, of O——, I was relieved of anxiety as to my machine, and I had still those two valued days of my leave to enjoy. Moreover, I had ample proof that the comradeship of those who use the King's Highway is not yet dead; after such an experience, who could doubt it?

WHARFEDALE.

THE DELIVERY OF MOTOR CYCLES BY ROAD.

THE other day a correspondent applied to the Petrol Controller's Department asking for a permit to deliver his motor bicycle by road to the purchaser, and received a letter saying that a permit under Clause 3 (F) of the Motor Spirit Restriction Order is not required if the vehicle is being used for professional, trade, or business purposes, *household affairs*, or for public duties. The words in italics are typed in purple, while the remainder is in black in the letter from the Petrol Department, so this infers that the delivery of a motor cycle by road to a man who has just bought it is allowed by the Order under the heading "Household affairs." But will all magistrates take this view?



Notes from Central Africa. Air Council. Old Time Motor Cycles.

PETROL SAVING IN THE SERVICES.

THE Petrol Executive has been impressing upon the Navy, Army, and Air Forces the necessity for further economy in the use of petrol. Leaflets and posters have been distributed saying, "Think seriously before using a motor vehicle or craft, or ordering it to be used."

* * *

THE AIR COUNCIL.

THE Air Council has been established by Order in Council as from January 3rd. It is constituted as follows: Lord Rothermere, Secretary of State and President of the Council; Maj.-Gen. Sir H. Trenchard, Chief of the Air Staff; Rear-Admiral Mark Kerr, Deputy-chief of the Air Staff; Commodore Godfrey Paine, Master General of Personnel; Maj.-Gen. W. S. Brancker, Comptroller General of Equipment; Sir William Weir, Director General of Aircraft Production in Ministry of Munitions; Sir John Hunter, Administrator of Work and Buildings; Maj. J. L. Baird, Parliamentary Under-Secretary of State; and Lt.-Gen. Sir David Henderson, Additional Member of Council and Vice-president.

* * *

AN OLD-TIME MOTOR CYCLIST.

COMPANY Quartermaster-Sgt. E. J. Bass has been recently mentioned in Despatches, and also awarded the Mons Star. Many of our readers will remember E. J. Bass as the enthusiastic hon. treasurer of the **Essex** Motor Club. He is still serving with the A.S.C., M.T., in France. In the early days he used to ride a 7 h.p. Peugeot as a solo mount, which was then one of the most powerful motor bicycles on the market. He writes from somewhere in France: "Just to wish all motor cyclists abroad, on the sea, in the air, and at home, as happy a Christmas as possible, and a prosperous and peaceful 1918. I hope this, my fourth year here, will be my last."

Quartermaster-Sgt. E. J. Bass.

MOTOR CYCLES AT THE FRONT.

WE have received the following communication from a corporal (R.E.), temporarily serving with the Belgian Army: "The motor cycles undoubtedly stand up to the work wonderfully. The Triumph predominates, owing to its strength, but *when shall we get larger tyres?* Sometimes we do get hold of 2½in. covers to fit 2¼in. rims, and what a difference where the comfort of the rider is concerned. With the 2⅜in. covers fitted, standard rims get smashed and dented beyond recognition, whilst the motor bicycles the Belgians ride (James, Rudge, B.S.A.) suffer very little, as their smallest tyres are 2½in. Please don't think this is a 'grouse,' but simply a small thing which would greatly improve matters, both for us D.R.'s and the machines."

* * *

FROM CENTRAL AFRICA.

WE have received from F. J. Astley, Captain and Chaplain, S.A. Motor Cyclists Corps, Nyasaland, the following letter describing the experience of motor cyclists in Central Africa:

"*The Motor Cycle* arrives regularly with every home mail, and continues to afford us constant edification.

"I notice in a recent number that Cpl. A. Hodgson, 4th L.A.M.B., has replied to the communication I sent *re* the taking of Godoma. There is no need for this subject to be the cause of further correspondence, but I will just comment on Cpl. Hodgson's two points.

First into Godoma.

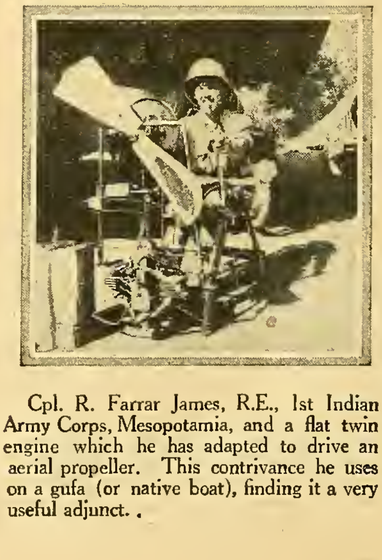
"First, that Cpl. Hodgson with another scout of the 4th L.A.M.B. was the first into Godoma—*i.e.*, before Lts. Hall and McHardie; these he met entering Godoma as he was returning to report to his O.C. I have laid this version before Lt. McHardie (Lt. Hall has been invalided home), who says he does not remember seeing anyone either returning from Godoma or already there when he arrived. However, for my part, I should be disposed to concede the point to Cpl. Hodgson, because it disproves Dvr. Miles Thomas's statement that the armoured cars were in before us. That could not be the case if Cpl. Hodgson's statement be true that he saw Lts. Hall and McHardie entering the town when he was returning to report. A remarkable echo of this episode has just transpired, and these two scouts will be interested to hear that they had a narrow escape. A German recently captured states that he was standing on Godoma Station platform with five or six others, and saw the cyclists pass over the railway crossing, which is only about a hundred yards from the station. As there were so many cyclists they did not wait, but decamped on mules through the native location. He did not see any cars.

Points re Machines.

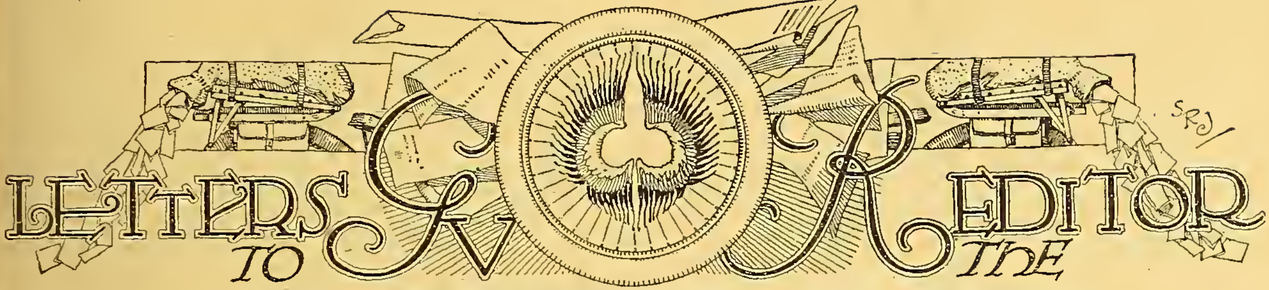
"The Douglas or any similar make is a fine little mount—if the difficulties in the roads are not stupendous, which they frequently were in this country, particularly after we passed 100 miles south of the railway. Until that time we had not experienced mountainous roads with surface of boulders for macadam. The L.A.M.B. riders travelled light, but every man of us carried kit and equipment weighing anything from 50 to 100 lb. For a long period two Lewis guns were carried on machines. Who would ask a light machine to do that day after day over roads which give them such a bucketing that, spare spokes form the mechanic's nightmare and rod iron is at a premium for reinforcing carriers?

"Again, the rainy season here is one long purgatory for the motor cyclist. Chiefly the surfaces were of white clay or black cotton soil, which latter is bottomless, like the nether pit, on the level and red clay on the mountains.

"We have just completed approximately 300 miles on our last run. There were forty-one miles stretch of sand. In its lightest parts it was a weariness to the flesh and a vexation of the spirit, but when it exceeded a foot in depth, even a B.S.A. with a low gear of 12 to 1 roasted up to furnace heat. In my opinion, however, it is the type more than the make which turns the scale."



Cpl. R. Farrar James, R.E., 1st Indian Army Corps, Mesopotamia, and a flat twin engine which he has adapted to drive an aerial propeller. This contrivance he uses on a gufa (or native boat), finding it a very useful adjunct.



LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address

DATE OF SECOND-HAND MACHINES.

Sir,—I should like to remark that I acquired a second-hand Humber motor cycle, wrote the makers *re* date, and received a courteous letter, giving date when the machine was despatched from their works.

Leeds. OSMONDTHORPE.

PISTON DESIGN IN TWO-STROKES.

Sir,—In reply to Mr. McDougall's criticism of the type of piston suggested by me in my recent article, I think he is under the impression which many motor cyclists have, that the pressure in the cylinder, even when both exhaust and inlet ports are uncovered, never falls below atmosphere. This, however, is not the case, for if the exhaust gases have a free passage out they cause a small amount of vacuum in the cylinder owing to their inertia. Thus, the piston can travel up on the compression stroke without encountering any resistance from the new charge of gas. At the same time, even if the cylinder were absolutely full of gas at the commencement of the compression stroke, a good fitting piston should be capable of holding any pressure which could be attained after it had passed over the ports in the cylinder walls. JAMES MARTIN.

FLYING IN A CURVED PATH.

Sir,—"Dyne," in his letter of January 3rd, is hardly happy in his suggestion of the earth as an example of a body travelling in a curved path under the influence of a single force. He has forgotten that the earth has an internal velocity of projection of the respectable order of eighteen and a half miles per second, which velocity (as there is no friction in the absence of a resisting medium in open space) would carry it on for ever in a straight line but for the sun's attraction, which causes the earth to curve towards the sun at the proper rate to travel round him in a closed curve.

The case is just the same as that of the projectile of a gun, if the resistance of the air be left out of account. The initial projectile force of the explosion would cause the shell or bullet to travel on for ever in a straight line but for the attractive pull of the earth, which deflects the missile downwards till it strikes the ground. To cause a shell to travel round the earth for ever, nothing is needed but some extra velocity if the atmospheric resistance were removed. A muzzle velocity of 26,000 feet per second would do it.

I suppose "Dyne" would hardly contend that a shell during its flight is acted on by one force only. And I question "Dyne's" assertion that a bicycle or motor cycle does not require extra power when making a turn. I think if he will try making a sufficiently sharp curve on a push bicycle he will find himself forced to pedal harder in order to avoid a spill. The change from a straight line to a curve requires extra power. Once the curve is established the extra power must be kept up to maintain it. "G.E.H." was quite right. The mere fact of a body following a curved path proves that at least two forces must be acting on it.

WM. F. A. ELLISON.

Sir,—I was very pleased to see "G.E.H.'s" letter in your issue of December 27th, 1917. I am glad to see that someone else has taken up the gauntlet I threw down, but am sorry Mr. W. G. Aston himself has not seen fit to reply to the criticisms he has received on the subject.

May I crave a little space to answer "G.E.H."?

He refers to very early machines, *i.e.*, the aero "tripehound" and the Blackburne. I do not think Mr. Aston thought of any time but the present in writing his articles. In any case, arguing on these lines we might just as well assume that because a 3½ h.p. motor cycle would not climb Alms Hill in 1904 it would not climb it now. Which, as Euclid is reputed to have said, is absurd.

So much for the past. "G.E.H." then proceeds to mention an occasion when a machine of official design lost 1,000 feet on a turn. "Why?" he queries. Naturally, one cannot say definitely. I may suggest a "dud" engine, poor rigging, or inferior piloting. But the most likely reason of all is probably that the machine was of official design!

Let "G.E.H." ask some of his friends in the R.F.C. their opinion of *officially* designed two-seaters.

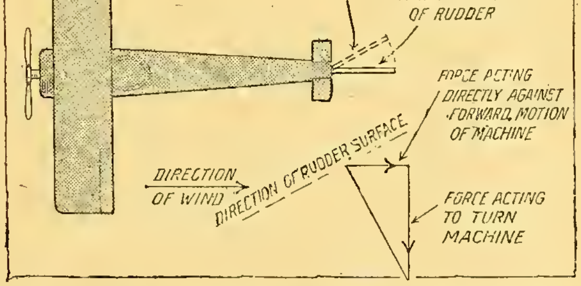
When embryo "birdmen" are learning to fly they are taught how to turn by keeping the machine turning for minutes at a stretch. Well do I remember careering round and round and round like any horse on a merry-go-round at a fair. Yet at the finish of air evolutions we were always higher than at the beginning. I particularly remember this because my instructor always used to ask our height when we had finished, and these were "pukka" steep turns, too.

Sometimes theory and practice *do* differ. I cannot profess to be much of a theorist, but modestly claim a fair amount of practical experience.

Many thanks to "G.E.H." for replying to my letter, and also to you, sir, for allowing me to waste so much of your valuable time. May I conclude in the hope that Mr. W. G. Aston will unbend and fell me with a shrewd blow? Like Mr. Asquith, I will w . . . F.M.C.H., LT. R.F.C.

Sir,—In your issue of December 27th, 1917, your correspondent "G.E.H.," Leeds, makes some interesting remarks with regard to aeroplanes, especially as concerns a machine's losing altitude when turning, and asks "Why?"

As we already know, the machine remains in the air only by reason of power being expended, and it is clear that, when the power available is decreased, the machine will fall.



"POSITION" OF RUDDER WHEN TURNING.
NORMAL POSITION OF RUDDER
FORCE ACTING DIRECTLY AGAINST FORWARD MOTION OF MACHINE
DIRECTION OF WIND
DIRECTION OF RUDDER SURFACE
FORCE ACTING TO TURN MACHINE

In the diagram, consider the rudder of an aeroplane. When the machine and rudder are in a straight line, as shown by the full lines, no resistance to forward motion is given by the rudder. In order to turn the machine, a sideways force is necessary, but, as shown, this is only obtained by introducing a retarding force also. The resistance of the machine is increased, with a consequent demand for more power. As the power available is assumed constant, the machine must gain the necessary extra power by gravity, and this, of course, necessitates a decrease in altitude.

Norwich. A.A.S.

MOTOR TRADERS AND THE NEW RESTRICTIONS.

Sir,—We feel sure that motor traders are themselves to blame for the drastic nature of the many restrictions which have been put on motoring, in so far as they have allowed each new restriction to be launched without any effective protest or opposition. No doubt there have been occasional protests from local or district organisations, but much more is wanted to meet with any possible success.

We trust that the lead we have taken in this matter may induce other traders to formulate ideas and suggest them publicly. If the traders of each district get together, resolve on a course of action, and appoint delegates, who would act in the traders' interests, for one grand central meeting, that would be a rough outline of the programme to be followed. The Government have already announced that restrictions will be placed on the use of coal gas; and if traders are to do anything at all, no time should now be lost in considering what we are to do.

ALEXANDER AND CO.

GOODS MADE IN GERMANY!

Sir,—It seems Mr. Chas. S. Ives has more supporters than you expected.

Allow me to express my opinion, and perhaps "Ole Bill" will not need to question my nationality if I say that I am a discharged soldier, and one of the lads who joined in September, 1914.

This war has been a lesson to the world, and every day brings some awful news of suffering. I can see no good coming from an after-war boycott; it will only breed hatred, and hatred is the seed of war. Besides, what is the use of killing German Prussianism if we set up the same kind of thing at home?

I think it would be far better if you used your spare paper—that is, if you must use it for such things—to create a more brotherly spirit after the war, and thereby live down the cause of it.

I did not join, and I feel sure very few joined, to help our profiteers to continue profiteering after the war, as would be the case if we allowed them to monopolise the market.

I have suffered through this war, but I shall buy and use the article that suits me best, be it German or any other make.

Your paper is far too interesting for me to "give it the sky."

TOM E. TANNER.

Sir,—Allow me to thank you for the lead you have given to the British press in reference to the above—a lead which, I trust, will be very far-reaching. In the December issue of *Impressions*, the editor of that paper asks his readers for their opinions on this very subject. Accordingly I have written giving him mine, and quoting from your correspondence pages. It seems a sign of the times that the best letter supporting your admirable attitude should come from a lady, "E.J.H.," in your issue of 27th December. The tone of the letter from Chas. S. Ives and those of his supporters is very remarkable, several of them suggesting to the proprietors of *The Motor Cycle* that their policy, if persisted in, will mean the paper's ruin. For the benefit of those readers who have not followed this correspondence closely, may I give some extracts from your issue of 3rd January?

"F. Jones," in support of "Ives," states: " . . . Now I am a strong believer in always giving honour to whom honour is due, whatever the make of an article is; and I call the Paris Resolution nothing but one to keep hatred up, and I think a paper like yours which is for sport . . " and finishes by threatening the proprietors that he and a good few others will stop taking *The Motor Cycle*. . . . This is followed by your Editorial Note: "Naturally we do not agree with the views expressed above, but as we wish to give all sides a fair hearing, we publish our correspondent's letter exactly as received."

"R.O.W." thinks "That gratitude for the Bosch magneto in the past should wipe away all bitterness regarding the horribleness of the Hun in this war."

Whilst "Leslie S. Broad" and "Ole Bill" write in the same issue expressing disgust at the sentiments set forth by Chas. S. Ives, Maurice Little, and others.

That men like Ives, Jones, etc., should use the word "sporting" in such letters as theirs is irony indeed. To you, sir, I take off my hat for the sporting attitude you adopt in adding such a courteous footnote to F. Jones's letter. Just think of it! A letter to an English paper, in which the writer (signing himself "Jones") swells his little chest and congratulates himself on "giving honour to whom honour is due." This in reference to Germans, be it noted! Apparently he has absolutely none for one of the first papers which boldly states that it will in future decline to handle money from a people whose actions are too horrible to put in plain type—poisoners of wells; murderers of old men and women, Red Cross nurses, and babies; who have crucified little children; cold-blooded murderers of British sea captains who attempted to defend their ships against the attack of submarines; whose women did not shrink to add to the tortures of British wounded; whose submarine commanders lurk unseen to strike (and who have struck) hospital ships crowded with helpless, suffering men, also passenger ships crowded with women and children, when hundreds of miles from land.

Surely all right-thinking men and women will agree with your attitude, and refuse to have dealings with such a people for at least a generation, or until it is proved beyond question that they are capable of honouring their promised word and of playing the game amongst the civilised and uncivilised peoples of the world.

I hope, sir, you will permit me to direct your readers' attention (especially Mr. Ives's and his supporters) to the strong, sane, and uplifting leading article in *The Times Literary Supplement* of 3rd January, entitled "The Hope of the New Year," from which these words are taken: " . . . they cannot believe lies for ever. They may believe them as long as the lies seem to benefit them, but when they profit them no longer they will not wish to believe them. . . . And what is most desirable of all is that the Germans shall recover their humanity; that the laws of the human mind shall work in their minds. 'God is not mocked.' That saying expresses the universal hope; but God will prove that He is not mocked by no revenge of ours—for revenge is His—but by the effect of their misdeeds upon the Germans themselves."

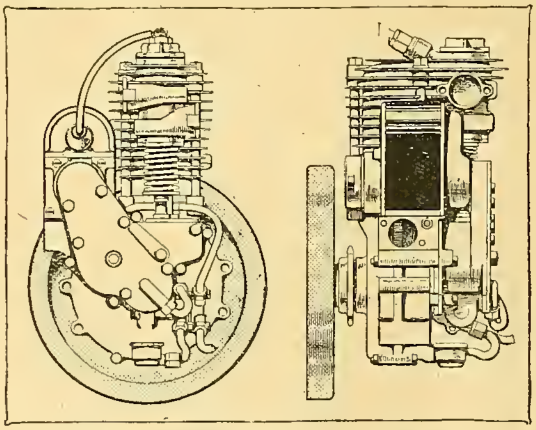
H. HORNER MAYNE.

THE IDEAL SINGLE-CYLINDER MOTOR CYCLE.

Sir,—I have before me an article by Capt. A. Lindsay—"The Future of the Single-cylinder Mount," in your issue of December 17th, 1916.

My ideal solo mount has 52in. wheelbase and a single-cylinder motor with a gear box chain transmission and shock absorber, plenty of power, minimum weight and c.c., high r.p.m., high compression and volumetric efficiency, automatic oiling, and carburetter, efficient cooling, low centre of gravity, and good balance.

I am now making a small number of a motor 70 × 90 mm., braking 7 h.p. at 3,000 r.p.m., with a magnesium alloy piston weighing 0.22 lb., and a very short connecting rod (1.5 times the stroke) to get a good volumetric efficiency at high engine speeds. The reciprocating parts are completely balanced, and also the revolving parts, through a very simple and reliable design. I am also testing a new valve design, and take air through the crank case.



An engine design submitted by a Swedish reader.

Stockholm, Sweden. HUGO MOREN.

DISTRIBUTION OF FOOD SUPPLIES.

Sir,—If only attention be promptly focussed upon our food and transport problems much may be done to minimise the evil effects of queue scandals. It is not of the smallest use to tinker with one aspect and leave the rest untouched.

The question of food supply naturally hinges upon those of food control and food transport. Your readers may be shocked to know that, while millions of our citizens spent Christmas in comfort, there were certain cases in rural districts in which families found themselves with no paraffin, no sugar, no tea, no margarine, and no meat except such as the unhappy labourer had in desperation picked up in a poaching expedition. Instead of finding remedies, the Food Controller seems to be adding difficulties. The farmer is bound hand and foot, so helplessly "controlled" that he can buy little, and sell nothing except under conditions that hamper, harass, and irritate him. Here, food abounds; there, people suffer for the want of it. Yet there are in the kingdom tens of thousands of idle petrol-less pleasure cars and thousands of others out of commission for want of new parts. The first should easily be available. Of the second, speaking from experience as scientific welders, at least 95% of the fractured parts could be restored to use by the welder within a few days.

There remains the question of propulsive power. This may not be so amenable to treatment immediately, but it can be dealt with. We have too long allowed the latent wealth of the Empire to lie undeveloped. Perhaps it will scarcely be believed that in one small area Overseas there are "in sight" a hundred million tons of oil-producing material, absolutely untouched, easily transportable by gravitation direct to tankers. We do not think it is creditable to us as a nation that parts of the Empire so rich in mineral wealth should so long be neglected.

BARIMAR, LTD.

SPONTANEOUS IGNITION.

Sir,—Judging from "C.R.E.'s" letter, it seems that he is not at all clear on the subject of the temperature of spontaneous ignition, due no doubt to the scantiness of detail available.

To quote Mr. Moore's paper in the *Journal of Society of Chemical Industry* of February 15th, 1917: "The temperature of spontaneous ignition is the temperature at which a substance, surrounded by oxygen or air at the same temperature, will burst into flame without the application of any spark or other local high temperature."

Mr. Moore's apparatus consists of a closed platinum crucible through which is passed a stream of air or oxygen. The crucible is situated in a heated block of metal, the temperature of which is measured electro-pyrometrically. The liquid fuel to be tested is allowed to fall, a drop at a time, into the heated crucible. When the t.s.i. is reached a slight explosion takes place, and the temperature indicated by the pyrometer is noted.

"C.R.E.," therefore, will observe: (1.) That the question has nothing to do with a gaseous explosive mixture. (2.) That oxygen or air, as the case may be, alone was present. (3.) The determination was carried out at atmospheric pressure, and that the question of pressure does not enter in, it being merely one of temperature.

The figures "C.R.E." quotes are rather meaningless without their attached explanation. Taking them as he gives them I should read them to mean that if a petrol air mixture is at a temperature of 364° F. and a pressure of 90 lb. per square inch, then the temperature of 986° F. must be reached before it will explode.

The second part of his deduction, however, tallies roughly with the figures of Mr. Moore. If air is compressed to 90 lb., as in a Diesel, the temperature rises 207° C. The t.s.i. of petrol is 370° C., therefore the original temperature must not be above 370 — 207 = 163° C. = 325° F.

The essential point about composite fuels, as shown in "Chemistry of the Internal Combustion Engine," is that they consist of a heavy portion, such as paraffin, and a more volatile part, such as ether, so that easy starting from cold may be assured. There are no figures available, but it is a safe assumption that the t.s.i. of a mixture will be the same as the constituent having the lowest value.

In the article just referred to reference was made to the subject of "cracking," and it was pointed out that fuels of the benzole, toluol type were more liable to this form of decomposition. "Cracking," however, only takes place at high temperatures, above red heat, which, in an engine, is only likely to occur in the gaseous portion during the actual explosion. If sufficient air be present a considerable portion of the carbon liberated through "cracking" will be combusted. The question of pre-ignition due to the formation of substances of lower t.s.i. may be ruled out, I think, as these bodies would be only momentarily formed in the course of explosion and immediately combusted. Experience does not show that bodies of the benzole class tend to pre-ignition.

Rochester. S. E. FOX.

Sir,—As a reader of your esteemed journal, I have noted the paper and correspondence which have recently appeared on the subject of spontaneous ignition. The variation in ignition temperatures determined by different investigators is extremely large, and I might point out that several other workers besides Holm and myself have obtained sets of figures still more widely divergent. I am at present engaged in investigating the reasons for these discrepancies, but am not yet in a position to make any definite statement.

Mr. Fox suggests that the ignition temperature of a fuel in the gaseous state is greater than that of the fuel in the liquid form. This theory naturally suggests itself from the figures by Holm and myself, but I am inclined to think that it is an incorrect conclusion. The ignition point of compounds is influenced by the complexity of the molecule, more complex molecules having lower ignition points. Most gases, being comparatively simple compounds, possess high ignition points. The actual conditions under which the experiments are conducted cause enormous variations in the results, which can only be accepted as comparatively correct. And although I have made many observations and read other people's publications with great care, I consider that it is the variation in conditions which affects the results, and not any difference between the ignition points of substances in the liquid and in the gaseous state.

I might point out that hot air intakes raise the maximum temperature of the charge with any given compression pressure, thus tending to promote pre-ignition. Also, hot air intakes lessen the weight of air drawn into the engine during the cycle, thereby decreasing the power of the impulse at maximum load.

With reference to the letter by "C.R.E." in your issue of the 3rd inst., I wish to point out that the ignition point can only be looked on as a relative value, and that the question regarding the effect of engine conditions—which are very complex—was treated in my paper in *The Engineer* of the 22nd June, 1917. The effect of certain mixtures was also noted.

It is difficult to say whether "cracking" takes place in petrol engines, but I should be inclined to think that this phenomenon does not occur to any considerable extent, as the common motor fuels do not readily undergo "cracking," and the carbon on piston tops generally originates from lubricating oil, or sometimes from the precipitation of carbon from the fuel, which is caused by the use of mixtures containing insufficient air for complete combustion, *i.e.*, too rich a mixture. HAROLD MOORE, M.Sc. Tech., F.C.S.

AVERAGE SPEED.

Sir,—Far be it from me to question the accuracy of any member of the B.E.F., but I cannot help thinking that when "Eldon" rode from Cheltenham to Tewkesbury in ten minutes (he said ten not eleven minutes in his first letter) the clock at Cheltenham must have been fast and that at Tewkesbury slow. I know this road well, and though most of it is straight, there are several cross-roads, and one very dangerous corner where an A.A. scout was always posted in pre-war days. Not only that, there is nearly a mile of traffic riding in Cheltenham, and I can only say that anyone who did the journey at fifty-four miles per hour, unless in the early morning, would deserve imprisonment as a criminal lunatic.

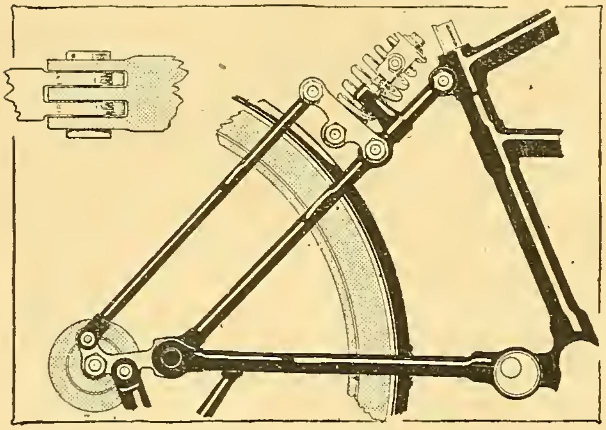
The maximum speed of which a machine is capable has little to do with the average speed if the rider observes the decencies of the road. Except on an absolutely straight road, where the rider can see at least half a mile ahead and see over the hedges and walls of all cross-roads, no one has any right to travel at more than forty miles per hour; and if he slows down to twenty miles for all blind corners, cross-roads, villages, and restive horses, not to mention stops for cattle and sheep, he cannot average more than 27 to 28 m.p.h. H.C.W.

MORE REAR SPRINGING.

Another Device that may be fitted to most Existing Machines.

MANY of the springing arrangements for motor cycles that have recently passed through the hands of the patent agents are supported by the names of well-known and respected firms, and there is no doubt that many riders will be anxious to try full springing on their favourite mount when the opportunity occurs. In our opinion, there is also a considerable future awaiting the patentee of the first really efficient device that is capable of being fitted to any machine.

The arrangement illustrated has this recommendation, but to avoid disappointment and unnecessary enquiries we will say at once that the conversion is not a few minutes' job. It is, of course, very improbable that any arrangement allowing of very simple conversion will meet with full success, because such a device will of necessity be of somewhat flimsy construction.



A rear springing arrangement that may be fitted to existing machines.

Mr. J. Warner, of Coventry, claims for his patent that it may be fitted to most standard machines, and that the conversion is likely to give satisfaction in service. Whatever may be said for or against the fitting, it is certainly of substantial design.

The Construction of the Device.

The most outstanding feature of the frame is, perhaps, the presence of a double back stay and the large spring underneath the saddle. The ordinary rear frame connections are retained, and the seat-pillar stays and other saddle stays are consequently in no way lessened in their rigidity. The rear fork ends, *i.e.*, the points of junction of saddle stays and chain stays, are converted, or rather replaced, by two hinged members, in which swivel a pair of links that are continued normally in a straight line and carry the wheel spindle in the ordinary way. It will be clear that as a result of this construction the wheel spindle is free to pivot and swing round the ends of the stay, the control of this movement being where the springing is brought into play.

Pivoted to each link, and bridging the wheel, is a yoke which is connected to a second link system placed immediately beneath the saddle, and also containing the controlling spring. This upper link system consists of two plates or bars, which are attached to the yoke (through a sleeve) by means of a bolt, and are similarly attached to the two saddle tubes, into which are inserted ball bearings, so that in this case the bolt will be free partially to rotate against the action of the spring on these ball bearings. The controlling action of the spring is exercised very simply as follows. Besides their two main connections the two links are also connected by a bolt, forming a bridge, placed midway between the yoke and saddle tubes. On to this bridge is fixed the spring in a more or less vertical position. The top of the springs rests in a U piece, which, of course, is pointing downwards. The two ends of this U piece are threaded, and are held in lugs brazed to the two rigid saddle tubes.

The Action of the Arrangement.

When the back wheel receives a shock, due to a road inequality, it swings round the two lower pivots and transmits the shock, *via* the yoke arms, to the upper side plates or bars. From these bars the shock, through the bridge already referred to, passes into the spring, where it is absorbed in the ordinary way.

One important advantage of this system is the ease with which the tension of the spring may be adjusted to suit the weight of any rider. As has been mentioned, the ends of the two U pieces are threaded, and the tension on the spring may be adjusted by means of lock nuts on these threads. Naturally, the greater the compression on the spring the less give is there to any road shock, and consequently the amount of tension necessary varies directly as the weight of the rider.

The inventor also claims that the fitting of a sidecar is in no way impaired by this system, and also that the device will work equally well whether the machine has a sidecar attached or not. The carrier is, of course, also sprung, so that a "pillion" passenger would also receive the benefit of the springing.

3D.

THE PRICE of THE MOTOR CYCLE

TO BE RAISED TO 3D. ON FEB. 7th.

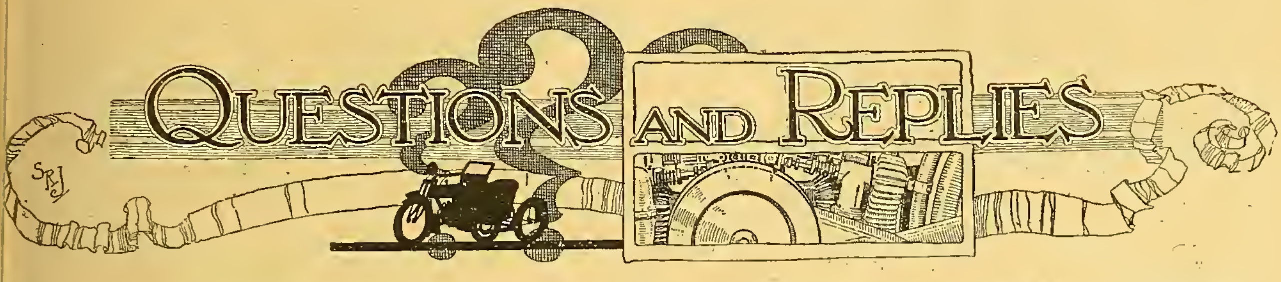
This further increase is necessary owing to the drastic restriction imposed on the import of paper and paper making materials during 1918 and the consequent heavy advance in the cost of paper, but the price will be reduced as soon as circumstances permit.

The subscription rates will be correspondingly raised on renewal or to new subscribers:

British Isles .. .. 15/2 per annum, post free.
All countries abroad.. 19/6 „ „

All subscriptions current at the time of reducing the price will be proportionately lengthened for the benefit of each subscriber.

QUESTIONS AND REPLIES



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Difficult Starting.

I have a 2½ h.p. two-stroke motor cycle, whose only fault is that it refuses to start without two or three injections; but on receiving an injection it will fire for about ten yards, and then stop. After repeating this two or three times, it will run perfectly. I have recently fitted new platinum points, and the timing has been checked and found correct according to *The Motor Cycle* handbook. It is fitted with a 1915 Senspray carburetter, and I have tried all positions of levers with no success.—R.S.

The difficulty in starting is undoubtedly ue to the cold weather and to the eavy petrol we are having at the resent time. Also the carburetter may e feeding too weak a mixture when ou attempt to start, and a slightly arger jet might be fitted and used during he winter months. We presume you ood the carburetter before attempting o start.

For Business Purposes.

Up to the present I have used my sidecar outfit for business and pleasure, and have always taken out the local taxation licence. Being now only allowed to use the machine for business and shopping (I live four miles from a town, four and a half from a railway station, and two miles from the nearest shop), is it absolutely essential to take out the licence if I am prepared to paint my name, address, and business on the sidecar? Nearly always on shopping excursions I have business to attend to—piano tuning—and so combine the two, thus being practically always on business. If painting name, etc., on sidecar will exempt me from taxation, will it be sufficient to disfigure one side only?—H.V.

You will not be exempt from the local taxation licence unless your machine is constructed and used solely for the transport of goods and merchandise—that is to say, unless it is fitted with a delivery box in place of a sidecar seat, and this is never on any occasion whatsoever throughout the year removed. Then we hold that you would be entitled to exemption from the tax, and would be also entitled to apply for a free-of-duty petrol permit. Painting the name on the sidecar body would not suffice.

20 m.p.h. Speed Limit for a 6 h.p. Twin.

I have a 1914 6 h.p. twin-cylinder motor cycle and sidecar. Lately it has taken to stopping gradually after attaining speeds of over twenty miles per hour. Also whenever it comes to a hill it loses power altogether, and I have to put it into low gear at once. I have cleaned out the cylinders and ground in the valves, and looked at the usual induction pipe joints, etc., but can find no cause for this stoppage. It is not "drying up," as the oil is the same as it always has had, and it goes through all right both with the automatic feed and by the hand pump. I have been a motor cyclist for eight years, and believe I know the usual causes of troubles on motors, but cannot detect this, and shall be very glad if you can advise me. The trouble is not overheating, as it will do it in the first mile from cold.—H.N.

Present-day petrol is apt to make up the jet in such a way that the partial stoppage is hardly noticeable when examining the jet, and by passing a needle through it the accumulation of foreign matter can be removed. You might try the effect of new plugs, but we rather think your trouble is due to the engine periodically starving for petrol. Make sure that the air vent in the tank stopper is not filled up, that your petrol level is correct, and that no air lock is occurring to hamper the flow.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY.

During 1918 the restriction on the import of paper and paper making material is very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week.

The Treatment of Accumulators.

My James combination is fitted with a Lucas dynamo lighting set. Under the new restrictions I have not had it running for over a month, and it may be another month before I have to use it again. But it must be ready at any time to take duty in the country. What is the best thing to do with the accumulators? As I cannot run the machine I cannot charge them, yet if I have to go out in the country I shall certainly want the electric light. Your advice will be much appreciated.—E.F.W.

You will have to have your accumulators recharged at a garage, say, every five weeks. It would be a good plan to switch one lamp on for a few minutes every week.

Throttle will not shut.

I should esteem it a favour if you would tell me (1) the correct way to adjust my Amac carburetter. When I start up the engine in free, I cannot stop by the throttle, but only by lifting the exhaust. (2.) I find the exhaust valve is badly worn about half way up the stem; is this the cause of a spitting noise in the silencer? (3.) Would you advise me to put in a new one, as I have two spare valves; and if I fit another, is there much trouble in adjusting it? Also the valve stem is a rather bad fit in the guide (in cylinder).—W.H.

(1.) Remove the gauze over the air intake of your carburetter, open the air lever fully, and then attempt to close the throttle. You will probably find that the throttle is hitching up near the bottom of its movement. If this be the case, it means either that the wire is too short or that it requires adjustment by means of the adjusting screw immediately above the carburetter. (2.) Quite possibly. A new valve should be fitted. (3.) On fitting it, grind it in lightly with oil, run the engine until it is warm, and see if the clearance at the tappet is correct. Probably the new valve will be a better fit in the guide. If the guide is really badly worn you should attempt to get another one, but spares are at the present time rather difficult to obtain. There is no difficulty in fitting a new valve; all that you have to make sure of is that the tappet adjustment is correct—about the thickness of the cover of *The Motor Cycle* between the valve and the tappet.

Sparking at Contact Breaker.

Will you kindly tell me whether there should be any sparking at the platinum points, and, if not, how I am to prevent it? I gather from my handbooks that it is the function of the condenser in a magneto to prevent destructive sparking across the points. Am I correct in my inference that the slightest spark is destructive? My machine is a 2¼ h.p. two-stroke of reliable make, and takes me merrily on my business with never a hitch, but my accidental discovery of the above-mentioned sparking has caused me a little worry.—D.J.B.L.

There should be practically no sparking at the platinum points. You are quite right, the condenser is intended to prevent a spark in the low tension circuit. Naturally the more sparking you get the more rapidly are the platinum points consumed. Excessive sparking is nearly always due to a defective connection in the condenser system. If the sparking is only slight and the machine runs well there is no reason for you to worry.

Unsatisfactory Running.

I have a 2½ h.p. two-stroke machine that has a curious and annoying habit which I am at a loss to explain. It starts easily enough on low gear and "revs." well, but as soon as the high gear has been engaged it refuses to fire on the throttle being reopened after the change. I have sometimes thought that it was worse when the engine was warmed up than when cold. At any rate, whether hot or cold, it will start on top gear without this misfiring. It seems a mystery to me, especially as I am always careful to get up a good speed before changing into high gear. The engine never overheats. I have suspected the magneto. The platinum points became very pitted and worn after the machine had done about 1,400 miles. I had to file them. About 600 miles further on they needed smoothing over again. Is it correct for a spark to occur at the points each time they break? This always happens. Also, will you please tell me why the points should separate .4 mm.? What difference would it make if they separated, say half-an-inch? I do not understand that, and have never seen an explanation of the limitation.—C.H.L.R.

We should say that the trouble is more likely to be due to carburetter adjustment. Try varying the size of your jet, and try a size larger and a size smaller than you have in already. What might happen is that the engine either chokes through too strong a mixture or the mixture is too weak—that is to say, when the engine slows down owing to a change of gear the mixture is not strong enough to enable it to fire. With regard to the magneto giving excessive sparking at the platinum points, this is almost invariably due to a faulty condenser connection. While it is impossible to eliminate sparking at the platinum points altogether, this should be reduced to a minimum. The reason why the platinum points should separate approximately .4 mm. is that this is a convenient space to give the requisite time of opening and closing and also to fit conveniently in a normal contact breaker. Thus, the magneto being timed and made to work at that gap, it is best to observe it.

Defective Alignment.

Will you kindly answer this query? If a sidecar combination drags towards the left hand, should the front of the sidecar be moved nearer to the motor cycle or farther away from it? This, of course, is referring to a sidecar fitted to the left side of the motor cycle.—K.C.O.

We should say that the sidecar and motor cycle were not in alignment with each other; in this case the front of the motor cycle should be moved rather closer towards the sidecar. Theoretically, the two should be quite parallel, both horizontally and vertically, and there is always a slight tendency to pull to the left on the part of a sidecar combination. This, however, should not be so great that it cannot be corrected with the least possible effort on the part of the driver. Possibly the weight of the sidecar passenger is too far forward, *i.e.*, not sufficiently over the axle.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

Explosion Queries.

(1.) How much power or speed is wasted by the compression stroke of a 3½ h.p. motor cycle? (2.) What volume of gas is drawn into the cylinder at each induction stroke, and what size of force pump (bore and stroke) would be required to deliver the same amount of gas, the pump working at engine speed? (3.) What is the greatest force of the explosion?—W.J.G.

(1.) The amount of speed wasted by the effort required for compression depends entirely on the initial speed of the machine. In most cases it is probably practically *nil*. If no explosion takes place, theoretically, there is no waste of power in turning the machine over compression, because the power required to accomplish this is automatically returned by the expansion of the gas after the piston has passed top dead centre. If an explosion is taking place, compression cannot be said to absorb any power, as the absence of compression would materially reduce the power of the explosion. (2.) The volume of gas drawn into the cylinder on an induction stroke depends entirely on the volumetric efficiency of the engine. As a rule, this is about 85%, so that in an engine of 500 c.c. the amount drawn into the cylinder would be 425 c.c. The necessary pump dimensions naturally depend upon the effective strokes of the pump. (3.) As a rule, the maximum explosion pressure is about 300 lb. per square inch on the head of the piston, the total force thus being 300 multiplied by the area of the piston in square inches.

A Legal Question.

I left my motor cycle and sidecar at a garage, saying I would call for it in a few hours. In the sidecar were two coats and a parcel, so I mentioned the articles to the boy in charge at the time, asking him if they would be safe during my absence. The boy said they would be quite all right, so I left the articles and went off. When I called back that night my wife's coat was missing—a black fur coat valued £3 10s. Another man was in charge then, and could not give me any information. The man would not take the garage fee I offered, so I called the next morning to see the manager. He said he was sorry to hear of my loss, but could not hold himself responsible for it. He admitted it was the boy's fault for not taking the things into the office and giving me a receipt for them. The boy happened to have a day off that day, and the manager could not say anything until he had seen the boy about it. I had to be back in camp on the Tuesday, so I could not call again when the boy was there. I left my address, then informed the police, but up to the present have not heard anything. Can I claim the value of the coat? I paid the manager 6d. garage fee, but did not get a receipt.—H.F.

In reply to your query, our legal adviser replies as follows: "As the garage proprietor's servant accepted the coats he assumed, on behalf of his principal, responsibility for them, and was bound to take reasonable care of them. Unless, therefore, the proprietor can show that he took proper precaution to prevent the coats from being stolen, he would have to pay damages to your correspondent."

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

The Forward 1/6

Two Points

that should stand out in the service of a fastener are—long wear and reliability.

FORWARD

fasteners embody those two points to a remarkable degree because, first, their roller bearings distribute the wear evenly and not on one side; secondly, the steel links are of unusual strength and will not break.

The long life, efficiency, and dependability which result from such a combination are yours to test.

Will you do so? First write for full details.

Thousands are being supplied to the Government.

Vevo Works, PARK LANE, BIRMINGHAM.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

MOTOR CYCLES FOR SALE.

Indian.

INDIAN 1914 7-9h.p. Combination, free engine, Millford sidecar, clutch, electrically equipped, speedometer, tyres good, fine condition; £41.—7, Codrington Mews, Blenheim Crescent. By appointment. [2739

7-9h.p. Indian, with 30 gn. Gloria sidecar, 3 electric lights, horn, speedometer, spring frame, kick, carriers for petrol, luggage, tyres, new Palmer, Dunlop, spare cover, tubes, 10 gns. worth spares, insurance; bargain, £55.—Jullerot, R.N. College, Greenwich. [2696

RIDER TROWARD and Co., 31 and 78, High St., Hampstead.—1916 T.T. Indian, 7-9h.p., clutch, perfect, 39 gns.; 1915 ditto, disc wheels, 39 gns.; another, 37 gns.; 1914 ditto, 33 gns.; 1915 7-9h.p. spring frame Indian and coach sidecar, 59 gns.; 1914 ditto, 49 gns.; 1912 Indian, 5-6h.p., cane sidecar, 2-speed, 29 gns.; 1914 spring frame 7-9h.p. Indian, 2-speed, 36 gns.; 1915 5h.p. Indian, 3-speed, 38 gns.; nearly new Indian coach sidecar, perfect, 11 gns.; also Indian, 2-speed gear, frame, mag., and engine.—'Phone: Hampstead 5392 or 4904. (D) [2641

James.

JAMES Combination, countershaft, chain, kick, smart, powerful; sacrifice price, or part exchange.—18, Gowlett Rd., Peckham. [2775

JAMES, all models, new and second-hand; extended payments or exchange.—Service Co., 292, High Holborn, London, W.C.1. [X0744

JAMES 1916 Combination, Lucas dynamo lighting, Stewart speedometer, price £78; extended payments or exchange.—Service Co., 292, High Holborn, London, W.C.1. [X0747

JAMES 1913 Coachbuilt Combination, 3 speeds, clutch, all new Dunlop tyres, lovely condition; £31/10; fitted for business purposes if required.—Bunting's Motor Exchange, Masons Av., Harrow. [2778

Lea-Francis.

LEA-FRANCIS, twin J.A.P. engine, 2-speed, countershaft, kick starter, footboards, oversized tyres, perfect running order, not used last two years; £32.—Lieut. Hunter Smith, c/o Merilees, Cedar Av., Chelmsford. [2734

Levis

LEVIS, 1916, 2-speed, 2¾h.p., only done 1,000 miles.—Box L5,382, *c/o The Motor Cycle*. [2786

1916 Levis, 2½h.p., Bosch mag., with lamps, complete, all in perfect order; a bargain, £23.—R. W. Burman, Elmdon, near Birmingham. [X0650

1915 2¾h.p. Levis de Luxe, Bosch mag., Senspray carburetter, 2-speed countershaft gear, as new throughout, small mileage; 28 gns.—Frank Stacey, Castlefields, Buckingham. [X0711

Matchless.

MATCHLESS 8h.p. Combination, new, fitted with J.A.P. or M.A.G. engines; extended payments or exchanges.—Service Co., 292, High Holborn, London, W.C.1. [X0746

MATCHLESS, 1917, 8h.p. J.A.P., War Model combination, complete with spare wheel, 3 electric lamps, mudshields, etc., brand new, not done 50 miles; price £105; seen in London.—Box L5,375, *c/o The Motor Cycle*. [2706

New Hudson.

NEW Hudson, 3½h.p., 3-speed, clutch, Bosch mag.; £33/10; E.P. or exchange.—Service Co., 292, High Holborn, W.C.1. [X0726

New Imperial.

CROW Bros., Guildford.—New Imperial, latest 2½h.p., 3½h.p., 6h.p. models in stock; also sound second-hands. [1047

1915 New Imperial-Jap, 2½h.p., 2 speeds, accessories, good order; £23, close offer.—Gwinn, Vicarage, Sheringham. [X0754

IMPERIAL-J.A.P., 2-speed, clutch model, £32/10; also new models in stock; E.P. or exchange.—Service Co., 292, High Holborn, W.C.1. [X0727

1917 New Imperial-Jap, absolutely equal to new; 32 gns.—Julians, 84, Broad St., Reading. 'Phone: 1024. Closed Wednesdays 1 o'clock. [0932

NEW Imperial-Jap, 1916, 2½h.p., 2-speed, E.I.C. mag., T.T. bars, mechanical horn, new tyre, all accessories, excellent condition, will do 100 miles to the gallon; £27.—Plummer, Rookwood, Luton. [X0631

NEW Imperial-Jap, 1915¾, 2¾h.p., 2-speed countershaft, 2 lamps, horn, accessories, new belt, Dunlops, recently overhauled, splendid road condition; £25, bargain.—S.H., Gordon House, Heanor Rd., Ilkeston. [X0682

NEW Imperial Motor Cycles, 2 speeds, clutch and kick starter, and lady's models in stock for immediate delivery; trade supplied; no permits required.—P. J. Evans, 91, John Bright St., Birmingham. [X0655

Norton.

NORTON, 1917 T.T. model, fitted with disc wheels, very fast mount; price £55.—R. M. Nesbitt, Hildenborough, Kent. [X0594

NORTON.—Big 4 Military Model, all-chain; also chain-cum-belt; £57/10; E.P. or exchange.—Service Co., 292, High Holborn, W.C.1. [X0733

NORTON, 1915, Big Four, chain drive, S.A. countershaft gear, C.B. side chair de luxe; £55 net cash, complete, 3 lamps, and one new cover and one retread.—C. Middlebrook, Church St., Preston. (D) [X0597

The Motor Spirit and Gas Restriction Order. Some Comments.

IN the words of the official notification to the press accompaning this Order, "Experience gained from two months' working" has enabled the authorities "to clear up points on which some doubt was found to exist."

From the continued correspondence on the subject from various readers of *The Motor Cycle*, it is quite evident that the previous Order was not clearly understood.

The definition "any inflammable liquid substance capable of being used for the purpose of driving internal combustion engines, whether such substance has been, or is liable to be, taxed or not," and the definition of gas—"any form of gas capable of being used for the purpose"—render it now quite clear that no fuel is left open to the motor cyclist if we except solid fuel, to enable him to use his machine as he thinks fit, so those who write to us and ask if paraffin or acetylene gas may be utilised now have a plain answer to their question.

The definition of a "private" motor vehicle means a motor vehicle on which the motor car duty is payable. This means to say that the sidecar machine used solely for business purposes cannot be held to be exempt from the local taxation licence, nor can its owner be entitled to receive free-of-duty petrol unless the vehicle is made exempt under the heading "trade vehicle," which means a vehicle constructed or adapted solely for use, and used solely for the conveyance of goods or merchandise in the course of trade, and whereon the full name and address of the owner are legibly painted in letters not less than one inch in length.

The Order also deals with the question of motor vehicles plying for hire. As these do not directly concern the motor cyclist it is only necessary to say that the most important alteration has been that, in future, motor cabs will not be allowed to ply for hire at a distance greater than three miles beyond the boundary of the area in which they are licensed.

The other principal points of the Order affecting motor cyclists are clearly enumerated in the brief extract which appeared in *The Motor Cycle* of the 10th inst., page 36. A few notes, however, concerning these paragraphs are desirable.

The paragraphs under the two headings, "Necessary Household Affairs" and "The Performance of a Public Duty," render it quite obvious for what purposes a motor cycle may be used by a private individual. It is very interesting to note that under the heading "Red Cross Purposes" those motor cyclists who still have their machines in commission may, if the medical officer of a hospital certifies that drives for wounded soldiers are necessary, perform the good work of giving these men an airing for a distance not exceeding twelve miles.

Yet another point worth emphasising is that it is permissible for the holder of a motor spirit licence or gas permit to deliver a motor cycle by road in connection with a *bonâ-fide* sale or intended sale of such vehicle, provided that the seller has obtained a permit from a superintendent or other chief officer of police in the area in which the motor vehicle is kept.

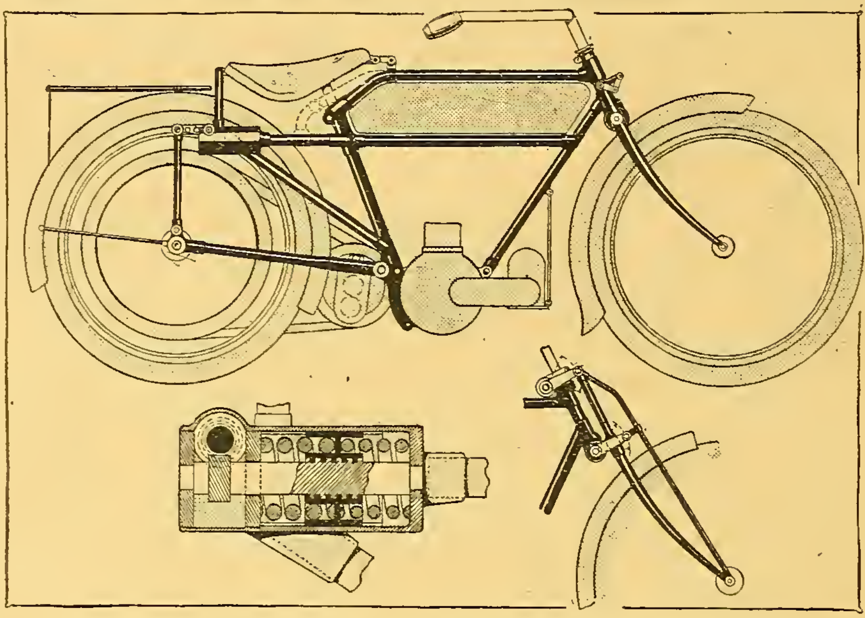
Mention was also made in our comments as regards the matter of special permits. These, of course, will be only issued under special conditions. It is possible that a permit will be issued to anybody, even if he be not the holder of a licence, who is anxious to deliver a machine by road to the prospective purchaser; to officers and men of the Services home on short leave from one of H.M. ships, or from one of the fighting fronts; and to a certain few highly privileged persons. Permits are not granted to Home Service men on leave.

The other chief novelty of the Order is that gas and petrol both now come under the same heading, but with this difference: that the quantity of gas is not limited, though its use is restricted in the same manner as petrol.

An index to the advertisements in this issue will be found on the page facing the back cover

FRICTION SPRINGING FOR MOTOR CYCLES.

A System combining the Properties of a Friction and Spring Shock Absorber.



A rear and front wheel springing device provisionally patented by Mr. T. Slaughter.

THE springing systems illustrated herewith are protected by Mr. T. Slaughter, 56, Parkside, Coventry, and aim at a combination of desirable features, without which any springing system must inevitably fall short of perfection. So far as weight and general adaptability are concerned, coil springs are infinitely superior to laminated leaf springs, and the only reason why the latter are so universally adopted in motor car and cycle practice is that, while possessing good springing properties, they also offer a certain frictional resistance which deadens rebound. A coil spring deadens shock as well as, or better than, any other type, but the great stumbling block in the way of its general use is that its reaction is so rapid and forcible that it is not conducive to comfortable riding. Obviously, then, if we can obtain the natural merits of the coil spring, and by some means deaden its rebound—as in car practice friction shock absorbers are used to steady the motion of the body—we have arrived at what contains the elements of a desirable springing system.

The manner in which the idea here shown is adapted to a motor cycle is a matter for the individual designer to decide. The idea is to throw the load upon the coil springs in such a way that considerable energy is spent in friction, so that hasty action of the spring is retarded.

The Working Principles.

The drawings are self-explanatory. Dealing with the rear portion of the frame, it will be seen that a barrel-shaped casting is located under the saddle, and contains two helical springs (shown also in section), one on either side of a travelling nut mounted on a very coarse pitch screw or worm. The nut is splined to the barrel and free to slide axially. To the end of the worm axle are attached cranks drilled for adjustment, and these are hinged to the rear stays in a suitable manner.

The heavy spring carries the load, while the lighter one absorbs rebound, the friction of the worm steadying the motion of the springs.

Two methods are shown by which the idea can be brought into practice for front wheel springing—the system shown in the drawing of the complete machine being in effect similar to the present Triumph arrangement. In this the shock absorber occupies the position of the central pivot. In the other drawing two shock absorbers are utilised, the arms that bring them into operation corresponding with the links of the Druid system.

The inventor states that a special feature of his idea is that the shock absorbers can easily be adjusted to suit the required load—a desirable feature, we admit, though we fail to see just how it can be brought into effect in the case of the front wheel springing. Perhaps adjustability for weight is more essential in the rear than in the front springing, but there is no doubt that adjustable front springing would be a very valuable asset.

AUSTRALIAN IMPORTS.

THE following statement is furnished by the Department of Trade Customs, setting out the imports into each State according to the country of origin:

Occasional Comments

"By Ixion"

A Curious Pre-ignition.

I SAT recently at the feet of a No. 8 hat who designs engines of umpteen h.p., and who was much annoyed with aluminium. You will be aware, gentle reader, that aluminium is, so to speak, too porous and crumbly to form the actual frictional surface of a motor cylinder, and to use it for that purpose would apparently be analogous to making files out of blanc-mange or stale bread, so they shove liners of steel inside their modern aluminium cylinders. This my friend had done so prettily that his engine weighed about two ounces per horse-power, and all the aeroplane designers of the Allied nations were sitting on his doorstep wildly waving cheque books at him. Unluckily, though engine No. 1 reminded him of his honeymoon for sheer cloying sweetness, engines No. 2 to umpteen pre-ignited at the compression of twenty atmospheres or so with which his maximum b.h.p. of 2,000 or so was partly secured. He lowered his compression down towards the modest ratio current in the humble world of motor cycles, but still this heartbreaking pre-ignition that twisted crankshafts into corkscrews and made con-rods wilt like candles on an August afternoon. I dare not tell you how many thousand pounds of his excess profits went to waste before he tracked the pre-ignition to its lair. Millions of sparking plugs lay littered round the test room floor, and every internal atom of surface was polished with rouge till it positively glittered. At last he found that in one or two patches of each errant combustion chamber there was no contact for conductivity between the liner and the jacket, and these isolated patches ran red hot just as the needle on the dial first flickered up towards the 2,000 h.p. mark. We live and learn.

Habitual Over-oiling.

I DOUBT whether any experienced manufacturer, rider, or repairer would query the assertion that motor cyclists, as a class, habitually over-lubricate. Nor are they to blame. Manufacturers for years past have supplied crude lubrication systems, and have safeguarded themselves by printing in their catalogues the maxim that it is cheaper to over-oil than to under-oil, in sublime oblivion of the obvious, but suppressed, consideration that it is impossible either to over-oil or to under-oil a properly designed engine. Thanks to the irritations of a crude lubricating system, further adorned by an inefficient sight gauge, very few owners take the trouble to master the oiling vagaries of their machines, and many of us ride by the rule of thumb—"when in doubt give it a pumpful." Consequently, the majority of motor cyclists use nearly as much oil in, say, 1,000 miles as a light car driver would use in the same distance. In the one case a 500 c.c engine is propelling a load of about 4 cwt.; in the other, a 1,500 c.c. engine is propelling about 15 cwt. Yet the oil consumption is approximately the same; and, even at that, the average light car consumes from two to three times as much oil as is absolutely necessary. In other words, the average motor cycle driven by an average owner very probably consumes about six times as much oil as is technically essential, and not all of the wastage is through the tappets either. There are canny owners of the dirtiest types of engines who, by keeping everything free and studying their adjustments, get a clean engine, slow carbonisation, and a low consumption at the price of much concentration. But the trade's ideal should be an engine which automatically keeps itself clean and automatically runs 4,000 m.p.g. of oil.

Revs or Anti-revs?

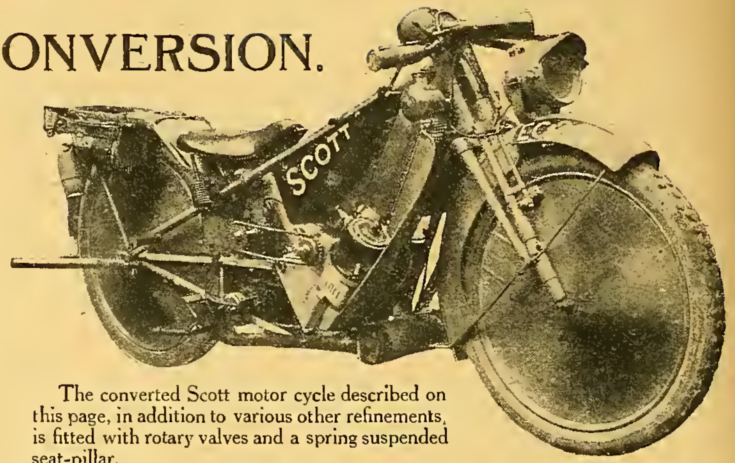
"MINORITIES must suffer—it is the badge of their tribe." But I always sympathise with minorities and I fancy this particular minority is a trifle unreasonable. Granting that you can get a glut of speed from a big slow-running twin, one must remember that such a machine would be little, if any, faster than a T.T. Norton; little, if any, better on hills; and about twice as heavy. The modern T.T. machine does not sell by the thousand, and the rival type of speed mount would not sell a quarter as well, simply because it is so clumsy to handle. Incidentally, many speed men want a machine that is fast on the level, and yet requires no humouring on hills, and this is where the variably geared revver tickles them as against the leviathan single-speed plodder. Want of *handiness* is largely responsible for the dearth of fast single-speeders. Secondly, the sidecar has exerted a colossal influence on design. The single-speed sidecar is *na poo*, a variably geared sidecar with the non-revving type of engine was apt to be a creeper on hills, and so we arrived at heavy, revving machines, capable of 40 m.p.h. on second. The makers design what will sell, and malcontents must not curse the press or the trade for the present state of things, but rather the public.

A Concession.

IT must, however, be admitted that nobody has seriously tried to make the best of such a type as the old 2¾ h.p. Excelsior or 3½ h.p. Quadrant in the light of modern knowledge. Now and again we strike a modern engine which reminds us of them by its dogged top gear work uphill but the experience is unusual. They would go practically anywhere on a 4 to 1 or 4½ to 1 gear, and they ran about 40 m.p.g. better than the modern 3½ h.p. without being anything like as fast. Moreover, unless memory betrays me, they were nothing like as pleasant to sit over. Perhaps some compassionate maker will notice that there are quite a lot of riders who continue to sigh over the lost possibilities of the old stolid type of engines, and will see whether he can in the light of modern knowledge make a roadworthy job of one.

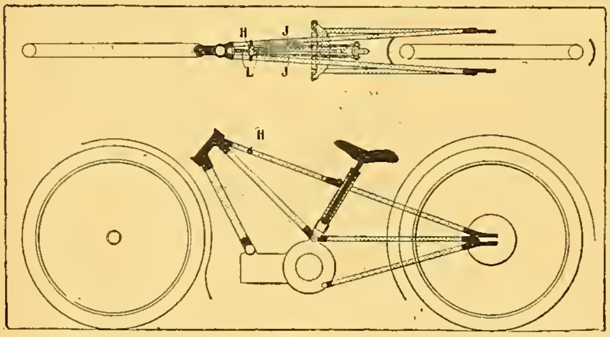
AN INGENIOUS CONVERSION.

Some Excellent Ideas carried into Effect in a Scott Motor Cycle.



The converted Scott motor cycle described on this page, in addition to various other refinements, is fitted with rotary valves and a spring suspended seat-pillar.

THE clever spring-seat frame design illustrated on this page is the work of Mr. L. S. Parker, of Messrs. James Parker and Sons, motor cycle specialists, of Kendal. It will be observed that the design permits vertical and longitudinal movement of the saddle, thereby affording the rider all the luxuries of springing, while in no way detracting from the rigidity of the frame. The illustrations below show the inventor's ideas for the application of the principle to a two-stroke machine to be known as the L.S.P., which he is designing, but the idea has been adapted to an ingeniously converted Scott, and has been put to a thorough road test, giving unqualified satisfaction hitherto. It will be seen that the bottom of the main seat tube is pivoted to the frame adjacent to the top engine support. The tube is of large diameter and contains a compression spring which intercepts vertical movement between the frame and the rider. In addition to this the seat tube is permitted an adjustable range of longitudinal movement, being suspended by the tension springs J J and the compression spring L, the latter acting chiefly to check the rebound. The bridge H is brazed to the two main struts running from the top of the steering head to the back wheel, so that the suspension of the seat tube in no way interferes with the general strength and rigidity of the frame. The frame, in fact, is a complete unit in itself, capable of withstanding all strains and stresses quite independently of the seat tube, which merely functions to support the rider. It will be observed that truly triangular construction is adhered to throughout, and the design would appear to be on excellent lines.



Frame design for L.S.P. two-stroke lightweight, with adjustable compound springing device. The principle has been adopted in the Scott conversion.

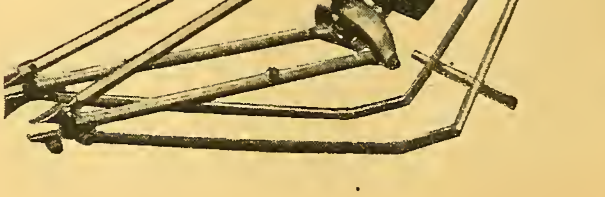
We are not informed what type of engine it is proposed to fix in the horizontal position shown in the drawing, which is a position we would venture to criticise. It would appear to us that a cylinder so placed is somewhat exposed, and there is not much advantage to be obtained by fixing an engine horizontally, unless the distribution of the cylinders demands such an arrangement.

As stated, the principles involved in the above design have been carried into effect on a converted Scott motor cycle, of which a photograph is reproduced; this certainly conveys the impression of being on very attractive lines.

An Ingenious Conversion.

It will be observed that the upper portion of the frame—that is, the two main struts running from the steering head to the back wheel—and similarly the suspended seat-pillar, have been added to the existing Scott frame, a large triangulated tank occupying the space in front of the saddle-pillar. These additions have increased very considerably the rigidity of the frame, quite apart from the comfort derived by the spring suspension.

Structural alterations have also been made to the engine, which, as will be seen from the drawings, has been fitted with rotary valves. The components of the rotary valve mechanism are shown in a separate illustration, the valve itself consisting of a sleeve running in a hardened steel liner. The inventor does not state what provision has been made for lubrication, but we gather that it would be a simple matter to take the drip feed supply directly through the outer casing of the rotary valve, thus permitting the oil first to circulate round the sleeve, then pass on to the respective crank case reservoirs. Petroil, of course, would



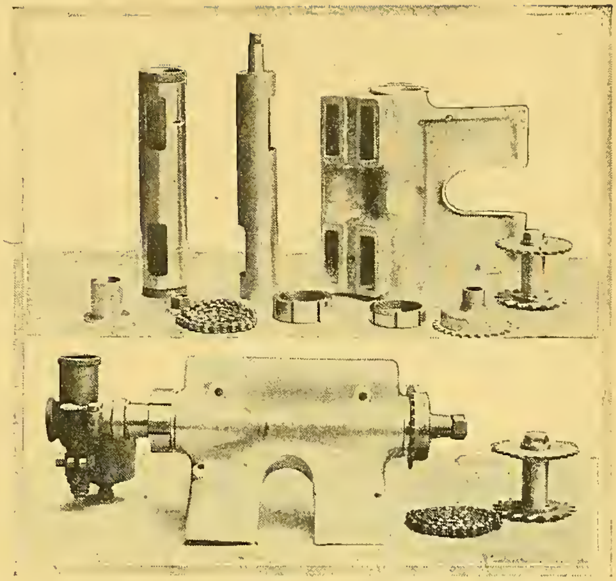
The frame of the converted machine, showing clearly what additions have been made to the original Scott frame.

An Ingenious Conversion.—

similarly solve the problem, and would, perhaps, lead to more even distribution of the oil.

The rotary sleeve is driven by a chain from the magneto, on the shaft of which two sprockets are fitted. The first sprocket takes the drive from the countershaft in the usual way, and the second, which conveys the drive to the rotating valve sleeve, is mounted on an extension of the magneto-shaft. This arrangement is not to be encouraged, as magneto bearings are not designed to stand the considerable drag thus imposed; in fact, magneto manufacturers are emphatic in their statements that it is preferable to drive a magneto by means of a train of pinions rather than by a chain, on account of the drag created by the latter.

We certainly think that Mr. L. S. Parker is to be complimented on his work, and on the attractive and sporting lines presented by the converted machine. Unfortunately, we have no details of the machine's behaviour on test other than that, as already stated, it has given unqualified satisfaction. If, however, the execution of the various ideas is carried out in a satisfactory manner, the machine should show many road qualities that will appeal to all classes of riders. Present-day developments tend strongly towards frame springing, and interest in novel engine design seems to have been seldom keener.



The rotary valve unit adapted to Mr. L. S. Parker's Scott. The two vertical members on the top photograph are the rotating sleeve and steel lining, the aluminium casting fitting on the existing crank case transfer port flanges. The bottom view shows the unit assembled.

A Board of Trade Publication.

A New and Valuable Series.

THE Board of Trade on January 3rd issued the first number of a new series of the *Board of Trade Journal and Commercial Gazette.* This new series is intended to cover the whole sphere of British commercial and manufacturing enterprise, and to give every information to business men and manufacturers likely to be of use in the development of their enterprises, and so of British trade as a whole.

Giving the All-clear signal in a London suburb.

The *Journal* for January 3rd contains a most valuable and instructive "Foreword" by the President of the Board of Trade, which contains most useful advice. The whole *Journal*, of course, is devoted to treatment of potential markets in all kinds of articles and all over the world.

Advice and an Appeal.

The following are two extracts from the "Foreword": "No Government Department can, in my opinion, secure success for our trade unless the traders and manufacturers themselves simultaneously put forth strong efforts on their own behalf. The ultimate success must depend upon the traders and manufacturers themselves.

"We propose to give the widest publicity possible to our daily work, and to open the door to suggestions and advice, and in return we ask for the great business world to meet with us frequently in spirit of friendliness and co-operation actuated by one motive only—the advancement of our trading interests in all parts of the world."

"Help us to make it possible to show through the pages of the *Journal* a constant and steady growth in our trade."

Another passage in the "Foreword" says: "The Board of Trade is being recognised and strengthened, and in an early issue of the *Journal* a full explanation of the changes will be published."

To the Wild Valley of Madeira.

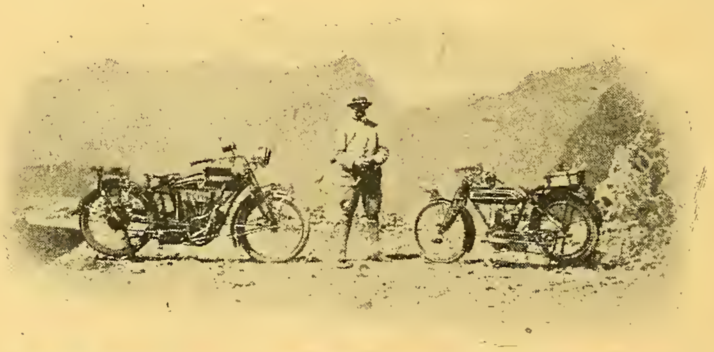
A 2½ h.p. NEW IMPERIAL AND A 7-9 h.p. INDIAN ON THE PASS OF ST. VINCENT.

NO, this is not another solution of the fuel problem; Fire Bicycle is merely the name that the rising generation of Madeira has for the motor cycle. The now familiar teuf-teuf of my New Imperial in the distance seems to have a spell akin to that of the pied-piper, and draws a swarm of swarthy little kiddies to the windows and into the streets to see the fire bicycle.

I have a mascot—a little brown monkey with a red collar and a blue hat—which perches on my front mudguard where the number-plate should be but is not, and this wards off accidents. It seems to be a never-failing source of joy to the juvenile population, and a perfect howl of delight goes up when they catch sight of it, while a dozen little hands point it out to me as though I had not noticed it before.

The Wild Valley.

Reliability trials, club outings, etc., are unknown here, consequently the enthusiastic rider has to fall back on his own initiative. As I had never been for a really long ride yet, I button-holed a pal—rider of a 7-9 h.p. Indian — and persuaded him to come with me on the next holiday on a lengthy tour. I had in my mind's eye a distant valley which cuts into the heart of the island from a considerable distance along the coast, aptly named in Portuguese "Ribeira Brava"—the Wild Valley. A new road had been lately built connecting Funchal with the village at the mouth of the valley, and leading up to a high and little-known pass at its head—the pass of St. Vincent.



In the "Ribeira Brava." Cooling the engines after a spell of low gear work.

Ours would be the first motor cycles to attempt this feat—a fact which added zest to our scheme.

We had heard that last winter's rains had wrought considerable havoc with the road, as it had not yet been paved; nothing daunted, however, we started off cheerfully one morning at 10.30 with full tanks, and lunch baskets strapped on the carriers.

Truly ignorance is bliss! What followed was one of the most nerve-racking experiences I have ever gone through. The first lap we did in fine style, all out for a considerable part of the way, and arrived at the village of Cama de Lobos with appetites whetted for what was to come, the road from there on being unknown to us. It soon became evident that there was some truth in what we had heard about the state of the road. Climbing steadily, we presently encountered a stretch six inches deep in loose sand, where it was all one could do to keep upright; this was followed by a piece of hard surface liberally scattered with sharp stones of a size varying from that of an apple to a football. The second lap, therefore, had all to be done on bottom gear, the engines rapidly warming up. Eventually, after several stops to cool down, we reached the summit of Cabe Girae, 2,000ft. up. Had it not been for the jibes of the scoffers who saw us start, we would now have turned back, but hoping for better luck we started off once more. What followed beggars description.

Although the road led downwards at a gentle slope, hardly ever was it possible to get into top gear. Potholes and ruts followed one another in endless succession, their monotony being broken at intervals by stretches of loose sand or a few hundred yards of rock-strewn earth track. We did not see much scenery this trip save for an occasional glimpse over some terrific precipice at the opalescent Atlantic far below, all our time being occupied in keeping our saddles. Arrived at the village, we swallowed several bottlefuls of "corpse reviver," and thus reinforced proceeded up the valley. The road improved slightly, and we had some opportunity of admiring the scenic wonders of the Wild Valley. Stupendous buttresses of weather-beaten rock towered to an immense height above us, thin whisps of mist crowning their lofty summits. Great fissures showed in the faces of the cliffs—proofs of subterranean energies of a bygone age. Pinnacle after pinnacle was marshalled in succession up the valley, and stood out like sentinels against the ethereal blue of the heavens, till the ranges finally merged in the central backbone of the island. At last, with red-hot engines we struggled up the last incline to the famous pass—the first motor cycles to reach it, and, I venture to prophesy, the last for a long time. From here a magnificent view was obtained down the two great valleys to the north and to the south, the sea being visible on both sides of the island through a haze of intervening mist.

To the Wild Valley of Madeira.—

We attempted to lunch here, but the banquet we had provided proved rather a fiasco; on opening the basket we found that eggs, sandwiches, meat-balls, cherries, and cakes had been mashed up together into a glutinous mass, which was doubtless very nutritious but hardly appetising. The return journey was much the same as the outward, consisting of skids, recoveries, bumps, jolts, and other phenomena of shocking roads with which most motor cyclists are acquainted.

The whole trip took us eight hours, and the distance covered was approximately forty-eight miles. Deducting two and a half hours for stoppages, this works out at an average speed of eight and threequarter miles per hour. The only trouble experienced was a stretched exhaust lifter cable on my machine, not a single puncture or breakage being sustained.

Both the Indian rider and I felt ill for several days after, and I had to tie a soft cushion on to the saddle of my machine for some time, in order to make riding possible.

Thus an Indian and a New Imperial together conquered what many thought to be impossible for a motor cycle. R.K.

Lubrication in Internal Combustion Engines.

The Object of Imposing an Oil Film between Bearing Surfaces.

THERE is no such thing as a perfectly smooth bearing. All bearings when viewed under a microscope are seen to have minute projections and declivities. These irregularities cause friction and abrasion when bearings are in motion. This fact is apparently realised by many professional racing men who use graphite with their lubricating oil. The graphite is supposed to fill in the irregularities of the bearing surfaces, and thus to present smoother surfaces which to some extent eliminate friction.

At the same time, however, the use of an oil is essential. If two sheets of plate glass, most carefully finished, are laid on each other it will be found almost impossible to move one over the other. If oil is interposed between the two movement is easy. If water is interposed between the two movement is still possible but with not such ease as with the oil.

Fluid Friction.

From the foregoing some idea may be obtained as to the reasons why oil is used as a lubricant. The oil spread over the glass has sufficient "body" and adhesion to withstand without rupture the pressure of the sliding glass, and thus maintains a layer of fluid between the moving surfaces.

The film of water, whilst not being entirely forced from between the surfaces, is ruptured in places, thereby allowing the two plates of glass to come into local contact, and consequently to produce more friction which has to be overcome by more power. It will readily be seen that where the surfaces touch, abrasion and consequently wear of those parts will occur.

Lubrication, then, is the art of the interposition of a film of fluid between bearing surfaces. This obtained the bearings are "floated," movement is facilitated by reduction of friction and wear is reduced for the same reason.

Gradual Pressure and Sudden Shocks.

It is a fact that there are steam engine cylinders which have been running for years and are to-day in as good condition as on the day of their erection. Such reduction of wear is impossible with the internal combustion engine owing to the fact that every power-stroke, and every obstruction met whilst running, transfers the shock of impact to all the bearing parts with possible rupture of the oil films between the bearing surfaces. It is generally understood that a body will withstand a constant pressure of many times the force of a sudden pressure.

This applied to the multitude of shocks received by the oil films will explain the comparatively short life of the bearing surfaces of an internal combustion engine. All internal combustion engine lubricating oils carbonise in use. The blue smoke issuing from the exhaust after a period of over-oiling is due to the absence of sufficient air to allow of complete combustion of the oil which has been volatilised by the heat of the engine. The carbon is then liberated in its free state.

Some of the carbon formed during an over-oiling period, and also some carbon from the carbonisation of the oil during the whole period of running, attaches itself to the inner steel parts of the engine owing to the affinity of steel for carbon at high temperatures.

The Desiderata of a Lubricating Oil.

The qualities needed in a lubricating oil for internal combustion engine use are:

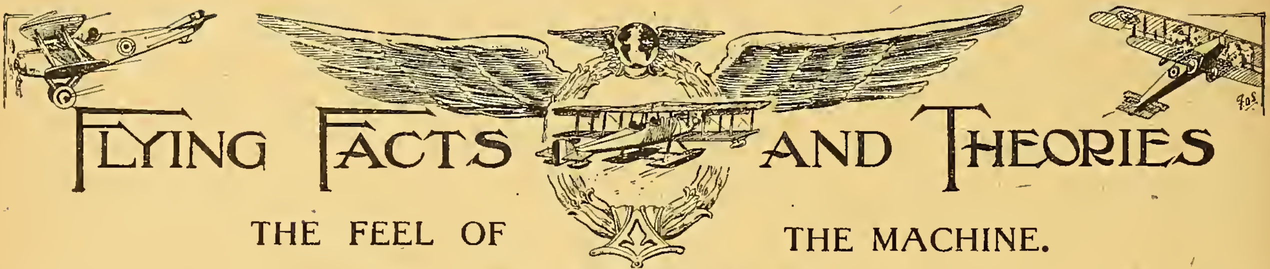
(1.) Sufficient "body" at the temperatures reached to withstand shocks without rupture.

(2.) Fluidity to enable a quick return to unruptured state after rupture.

(3.) Burning point sufficiently high to withstand without excessive volatilisation the temperature of the engine.

As all of these qualities cannot be obtained in their highest degree without injury to another quality, a compromise is effected by oil manufacturers. The whole subject of lubricating oils and lubricating theory is indeed in a rather undeveloped state at the present time, and there is ample scope for research and experiment.

All these internal combustion engine oils contain mineral hydrocarbon oils of different series and sources. The chief sources are the United States and Caucasia. The crude petroleum oil is found naturally oozing from the ground or is reached by boring. The crude petroleum is refined by distillation in stills. The most volatile and inflammable of the hydrocarbons form the first distillate. The lubricating oils are obtained towards the latter end of the distillation, and also from the residue in the still. These fractions form the least volatile of the hydrocarbons contained in the original crude petroleum, and by chemical manipulation and filtration the final lubricating oil is obtained. R.M.



FLYING FACTS AND THEORIES

THE FEEL OF THE MACHINE.

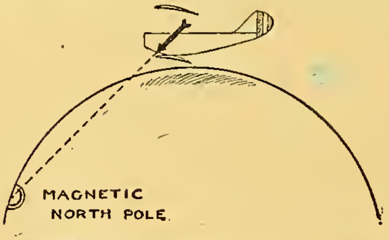
By W. G. ASTON, A.M.I.A.E.

THE points raised by some of my opponents, notably "O.J.F.S.," with his professed dependence upon the "feel of the machine" as a source of information, suggest that it may not be without interest to consider to what extent a pilot may know what he is doing when the atmospheric conditions are such that he cannot see the earth. If only the machine itself is visible it is obvious that no direct visual indication is given which can determine its position or motion in space. It may be, for all the pilot is made aware through the sense of sight, equally well looping the loop, climbing, diving, side-slipping, turning, or flying upside down, as travelling straightforward. If the machine is cut off from the earth by a sea of cloud, though itself is flying in comparatively clear air, conditions are by no means so bad, since certain features of the cloud-sea will act as relatively fixed points in space whereby the pilot can tell if he is turning or otherwise going off his course, and detached clouds above the "sea" will similarly prove useful guides. The worst possible weather conditions are snowstorms and fogs, since neither of these has, as it were, any bottom through which the pilot can descend into a clearer atmosphere, hence a safe landing is rendered exceedingly difficult. As far as knowledge of what the machine is doing is concerned, however, the results are the same if the conditions are such that no landmark whatever (and this term includes cloud features) is visible.

Human Sensations.

Fortunately, sight is not the only sense which can indicate what is happening to the aeroplane, and also, fortunately, no amount of cloud, fog, or snow can possibly affect gravity. Fortunately again, the organs of the human body are so nicely suspended and so sensitive to changes of motion that it is in itself an excellent form of accelerometer, if an inaccurate one. Thus the pressure between the person of the pilot and the seat which carries him will undergo a great increase if the aeroplane loops the loop or executes a sharp turn, and this increase of pressure will instantly apprise him that the desired straight course has been departed from. Conversely a change from level flying to a dive will produce a decreased pressure. In certain circumstances this gravity effect may be so high as to cause actual faintness owing to the excessive pressure on internal organs. Unfortunately the human body is not a sufficiently delicate accelerometer to answer to small deflections, and the senses are therefore incapable of registering any but very big variations from the normal course. Even granting that a pilot knows the aeroplane is turning, by his susceptibility to sensations of acceleration, it is almost impossible for him to know, without other evidence, in which direction he is turning, for the same reason that we are ordinarily totally unaware of the direction of the earth's rotation without consulting the sun or a compass.

Recourse has consequently to be had to instruments, and of these the one for which the most obvious need arises is a compass. At first glance it would appear that this can be made easily to show deviations from a straight course even when no external object is visible, but unfortunately such is not the case. It is true that a practically perfect compass can be made, but most compasses fall very far short of this ideal, so that one will not infrequently hear pilots remark that, as soon as they got swallowed up in a dense cloud, "the compass went mad and spun round." The reason of this is as follows. Imagine an aeroplane, fitted with a compass, flying horizontally towards the north. The compass needle, viewed from above, will lie along the axis of the machine, but since, as shown exaggerated in the sketch, it points towards the pole, it, looked at from the side, will be at an angle with the horizontal plane of the machine. This angle is known as the "dip," and in order to counteract it the south-seeking end of the needle is provided with a suitable balance weight, which pulls the freely suspended needle level.



The effect of magnetic dip on a compass needle in an aeroplane.

Faults in a Compass.

Now supposing the machine turns westwards, this involves the introduction of an acceleration acting from right to left. The effect of this acceleration upon the unsymmetrically balanced needle will cause the heavier, south-seeking, end to swing outwards to the right owing to its greater inertia, and therefore the needle, whilst the machine is in such a turn, will tend to remain in line with the axis of the aeroplane, and will consequently make it appear that no turn is taking place. This phenomenon is called the "northerly turning error," and must be eliminated from a compass if it is to be universally effective as a directional guide. When the machine is travelling south this disadvantage does not exist, as, supposing it now to turn towards the east, *i.e.*, towards the left, the needle will immediately show the smallest turn, and moreover show it to an exaggerated degree. To guide oneself whilst flying southwards, or in any direction from east to west, through south, is therefore

Flying Facts and Theories.—

an easy matter. It can easily be appreciated, however, that under the influence of changing centrifugal force the ordinary compass can easily "go mad," though it is nevertheless a perfectly satisfactory instrument if, and when, the pilot can correct himself by means of any "landmark."

Turning now to other instruments, we have, first of all, the air speed indicator. By its side will be an engine revolution counter, and much valuable information is furnished by a close consultation, and correlation, of these dials. Also there is the much-despised level or "bubble" instrument, and the aneroid barometer. The former is practically a very coarse spirit level, and the central position of the bubble indicates that the lateral control of the aeroplane is correct, whether it be flying straight or on a curved path.

The Air Speed Indicator.

Now let us suppose that at 1,500 r.p.m. of the engine the air speed indicator shows 100 m.p.h. when the aeroplane is flying level. If the r.p.m. remain practically constant and the air speed drops off, then the machine must either be turning or climbing, or both. If the air speed increases, then the flight path of the machine must be downward. In either case the descent or ascent, if sustained for only a short time, will be visible on the aneroid. The maintenance of a constant air speed with a constant r.p.m. (*i.e.*, a fixed throttle opening) may be taken, in conjunction with previous observation as to the appropriate figures, to be evidence in favour of a straight course, apart altogether from the behaviour of the compass, though it is not necessarily conclusive, even though the joystick be in the middle and the rudder bar be in its usual position.

The "level" will indicate big "yaws" or sideslips, but it will not easily show up very slow ones.

Some other instrument is therefore requisite for maintaining a straight course in the absence of the ideal compass, though no doubt "O.J.F.S." and others will quickly and justly object that there are quite enough "comic speedometers," etc., already. Either one can have a gyrostat, which for a short period would give one a definite direction, or one can install a device for indicating when the aeroplane is turning and to what extent it is so doing. Both these instruments are perfectly practical, and of the two the latter is undoubtedly the more useful, as by avoiding turns and holding on to a straight course one can coax a refractory compass into sensible behaviour irrespective of the direction in which one is travelling.

Provided they are constantly consulted, the instruments mentioned above, formidable in array though they be, do at least throw a certain amount of light on an otherwise dark situation, especially in conjunction with the pilot's own "sense" of gravity. It is, indeed, difficult to imagine that a series of loops, an upside-down position, a violent sideslip, a rapid climb or dive, whether straight or of the "spiral nose" variety, can be indulged in, and persisted in, unknown to the aviator. A really perfect compass, of course, would materially relieve the troubles of the lost pilot, and the time is probably not far distant when the problem will be satisfactorily solved and this ideal instrument be a standard fitting on all machines.

In the meantime, it is not to be denied that flying in atmospheric conditions which do not permit the pilot to have a direct visual idea of what he is doing is fraught with considerable risk, the gravity of which is dependent upon the structural strength of the machine, since he may perform evolutions, in a vain attempt to get a "mad" compass back to comparative sanity, which will impose dangerous stresses on material. One can hardly blame a pilot, not thoroughly "air-hardened," for suffering from a slight attack of panic in such circumstances.

The Advantage of a Stable Aeroplane.

This is, needless to say, where the thoroughly stable aeroplane shows its great advantages, for no matter in what position it gets, it can always be relied upon to come back to a normal attitude if left entirely to its own devices. I hope to explain some of the reasons why this is so in future articles.

As to what is best to be done when "lost" in space depends upon circumstances. No cloud is infinitely big, and the preservation of a tolerably straight course will bring one out either above or below it, or at one side or the other. Heavy long-continued snowstorms and fog—the two worst enemies of flying—rarely arrive unexpectedly, though it is not difficult to imagine circumstances—long-distance bombing, for instance—in which they are liable to be encountered with no chance of avoidance.

In the ordinary way the difficulty of knowing what one is doing is not complicated by darkness; if the cloud, fog, or snowstorm be dense enough one can see as much, or as little, by night as by day. At night, however, tenuous ground mists that would be sufficiently transparent by day, often appear as opaque as a blanket, but even on the darkest night will probably have sufficient radiance to provide some sort of visible horizon as a basis for direct visual control of the machine. In such an event the additional risk is solely concerned with the ability to make a landing. In the absence of such mists nature has very considerately provided in lakes, rivers, canals, and so forth, areas of radiance which unfailingly catch all available light from above and so provide a practical landmark or horizon.

The Importance of Weather Conditions.

It is because of the value to flying men of accurate predictions of weather that the science of meteorology has acquired such enormous importance in recent years. However perfect in control and economical in fuel the aeroplane is made, it must eventually come down to the earth from which it started. Instruments already in existence are capable of telling a pilot pretty well all he wants to know once he is well up in the air, but no instrument conceivable can show him how to make a landing on ground that is scarcely visible twenty feet below him. The only remedy is, therefore, not to ascend when such weather conditions are likely to arise, and it is to meteorology that one must look for the desired prognostication.

Special Note.—In the ninth line of the left column on the second page of the article on "The Influence of Altitude," which appeared in *The Motor Cycle* for January 10th, the following words appeared: ". . . provided the altitude remains unchanged." This was a printer's error, and should have read: ". . . provided the attitude (*i.e.*, of the aeroplane) remains unchanged."—W.G.A.

NOTES ON THE USE OF GAS IN PETROL ENGINES.

FUEL LOSS AT CARBURETTER.

1918 MODELS.

Women Motor Transport Drivers.

An Army Council instruction recently issued states that women motor drivers for service at home will be supplied by the Women's Legion, while those for service abroad, other than those working under V.A.D. organisation, will be supplied by the W.A.A.C. When a member of the Women's Legion wishes to serve abroad she will be required to transfer into the W.A.A.C.

Motor Cycling Club.

We are asked to announce that the annual general meeting of the above club will be held at the Monico, Piccadilly Circus, on the 30th inst., at 6.30 p.m., when the accounts for the past year will be presented. It is hoped that any member who sees this notice will make a special effort to be present, and will accept this notice as adequate. As the secretary points out, it is practically impossible to ascertain addresses in the usual way at the present time.

May Petrol be used to attend Religious Services?

Two prosecutions under this heading were reported in our issue of December 6th, one of the cases being dismissed, though in the other the victim (a lady) was fined. The dismissed defendant was a Roman Catholic, and another Roman Catholic (a doctor) recently had the case against him dismissed at Cambridge.

By the *very latest* Order, however, the use of petrol for attending religious services has been definitely forbidden.

Petrol for Coal Miners.

The Auto Cycle Union has done very good work recently in obtaining petrol licences for coal miners, to enable them to ride to and from their work. The other day a Welsh miner wrote to us, and stated that he had been unsuccessful in obtaining any petrol after making due application. We referred him to the secretary of the A.C.U., who took up his case, with the result that he was immediately successful in obtaining a licence for two gallons of petrol per month. This goes to prove that very often when individuals apply to a Government body for a concession they are unable to put their facts forward with sufficient clearness, but when the matter is taken up by a well organised association matters appear in a very different light, and the request is granted.

Imports and Exports. A Record Year!

During the last few months there has been a gradual decrease in the importation of motor cycles, tyres, and accessories. In the month of December the value of the imports was £1,691, a decrease of over £1,000 on the November figures. The number of motor cycles imported was two, valued at £22. What machines they were is difficult to imagine, considering the low amount quoted.

Exports.

The exports for December did not reach those of the previous month, but were higher than those of December, 1916 and 1915.

The total number of motor cycles exported during 1917 was 13,981, as against 12,847 in 1916 and 10,927 in 1915. The value of these (with parts) eclipses all previous records, being £1,216,356. The previous best was in 1914, and totalled £1,168,799. In no other year has a total of £1,000,000 been reached.

	1915	1916	1917
Number of machines ..	1,065	691	867
Value of motor cycles, parts, tyres, and accessories	£90,545	£54,867	£95,907

Petrol Imports for December.

1915	1916	1917
12,983,382	4,100,853	9,556,120

The number of gallons imported during the other eleven months of 1917:

January	13,001,740
February	12,257,984
March	9,246,546
April	10,258,951
May	12,270,934
June	11,327,434
July	12,346,846
August	7,853,368
September	13,278,972
October	13,887,674
November	14,269,893

A Kick-starter for the Zenith.

A reader writes: "Some time ago, at the request of one of your readers, there appeared in *The Motor Cycle* a few articles on home-made kick starters for Zenith machines. I have tried most of these devices but found none of them a success. I would like you, not only on my own account but on that of the large number who ride direct-driven Zenith machines, to invite readers to give their experiences of other home-made kick-starters."

Yankee Talk.

In describing new Indian models an American paper refers to "a horizontally-oppressed twin." We have heard of Yankees who cannot get *accustomed* to the English accent, but we feel simply *overpowered*.

Petroleum Controller for Egypt.

Note that it is a petroleum and not a common-or-garden-petrol controller they are to have in Egypt. In this country petroleum according to the Act, probably paraffin or kerosene according to common parlance, is used more extensively for heating, lighting, and industrial purposes than it is in England, and although some of the fuel is produced in Egypt, much has to be imported. Hence another controller is to be added to the list, which is already alleged to occupy as much space and paper as "The Britannica."

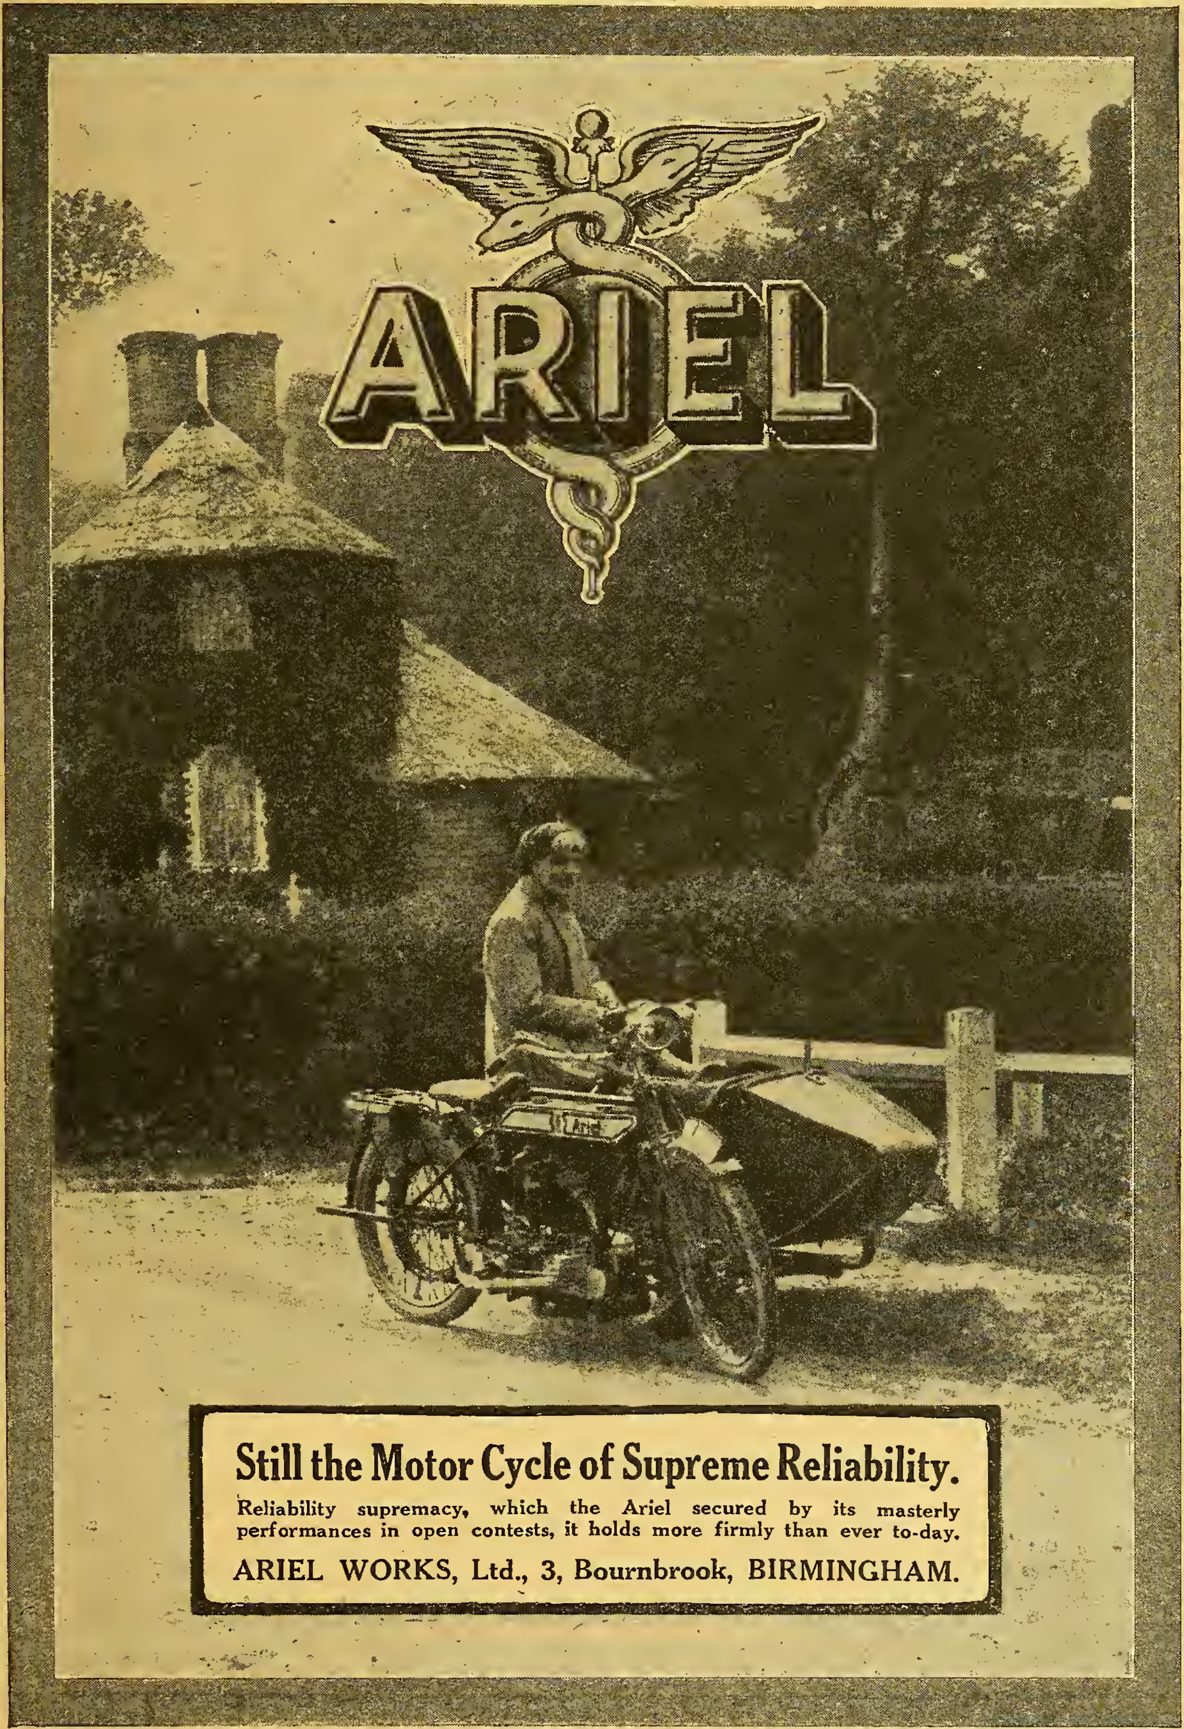
American Liberty Loan.

The Liberty Loan campaign, of which Mr. Walter Davidson (president of the Harley-Davidson Motor Co.) was one of the committee, has proved an unprecedented success. The quota allowed to Milwaukee was £5,000,000 as a maximum, but over £6,000,000 was subscribed, well over 30% over the maximum allowed for that district.

These figures, taken in conjunction with the success just obtained in the recent Liberty Loan, speak well for Milwaukee's enthusiasm.

Electricity instead of Petrol.

Cable advices from New York show that President Wilson is taking personal interest in steps to bring about petrol economy without undue disturbance of transport interest. He has agreed that every encouragement shall be given to the continued output of electric lorries both for home trade and export to the United Kingdom. The U.S.A. Aeronautical Department has purchased the rotary engine division of the Long Island City Factory of the General Vehicle Co. for £500,000, but the terms of the Government contract expressly protect the electric vehicle departments, and every facility will be provided for their increased production if required. It is understood that the present depletion of transport in the United Kingdom largely accounts for the decision not to interfere with the General Vehicle Co.'s export trade.



Still the Motor Cycle of Supreme Reliability.

Reliability supremacy, which the Ariel secured by its masterly performances in open contests, it holds more firmly than ever to-day.

British Magnetos.

It is announced that up to the end of the year 1917 the members of the British Ignition Apparatus Association had manufactured and supplied over 300,000 British magnetos.

Altitude Record.

Flight-Lt. F. B. Papa, of the Italian Army, on a Sia-Fiat biplane, has beaten his own previous height record when carrying a passenger by nearly 2,000 feet, attaining a height of over 23,000 feet (4½ miles). The engine fitted to the biplane was the same type of Fiat as the one used for the Turin to London flight.

New Petroleum Supply.

Eight hundred and fifty-nine new oil wells have been started near Los Angeles, California, in an oilfield estimated to cover two thousand acres. From one well alone oil is flowing at the rate of seven thousand barrels a day. The exportation of oil from the United States now reaches eight million to nine million barrels a year, which is three million to four million barrels in excess of the 1915 figures.

Petrol for Wounded Soldiers.

It is generally understood that wounded and convalescent Service men who are also the registered owners of motors shall be granted pretrol licences, and also permits to use their vehicles whether cars or cycles. A wounded officer in that home of culture and enlightenment—the North—has recently had a case against him dismissed on payment of costs as a great favour by a bench of magistrates of usual intelligence and with all prejudices complete.

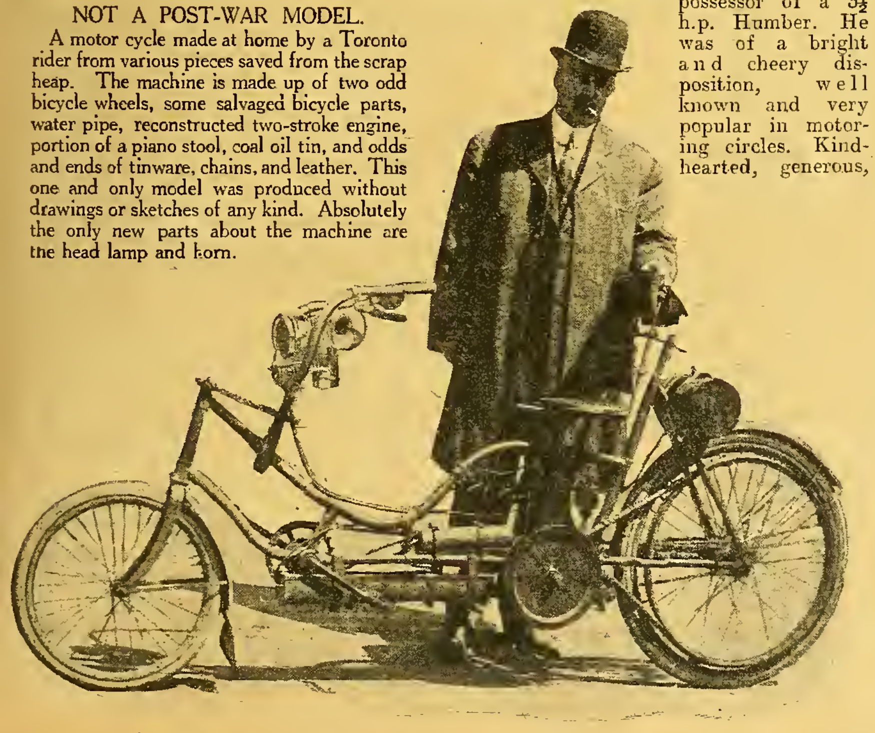
As a matter of fact, although the granting of a petrol licence to a wounded soldier is quite legitimate, the unfortunate applicant cannot always be sure of success. A member of our staff in this position has had some almost humorous replies to various applications made on these grounds, but they have all been of a consistently negative nature.

Anonymous Contributions.

We have often called attention in these pages to the necessity of correspondents sending their names and addresses, not necessarily for publication, but for the benefit of the writer of the letter. Here is a glaring instance. A wounded officer applied to the Petrol Controller's Department for a licence. The Petrol Department held up his application, and did not grant the permit until an interval of six weeks had elapsed. As our correspondent only signs himself "Wounded Officer," we must refrain from publishing his letter, and are also prevented from taking up the matter with the Petrol Controller's Department. If, however, "Wounded Officer" will send us his name and address, we will gladly take up the matter with the Department, with the idea of preventing others from being treated in like manner.

The Late Mr. H. J. Swindley.

We greatly regret to have to announce the death of Mr. Harry J. Swindley, so long connected with our parent journal *The Autocar*. He joined Messrs. Iliffe and Sons Ltd. about thirty years ago, and was an enthusiastic cyclist, holding the position of London Editor of *The Cyclist* for a great many years. When the motor cycle came into prominence, and before this journal was started, *The Cyclist* devoted a certain amount of its pages to the self-propelled bicycle, and the late Mr. Swindley used then to contribute the motor cycle notes. His best love was always the pedal cycle, though for a short period he was the possessor of a 3½ h.p. Humber. He was of a bright and cheery disposition, well known and very popular in motoring circles. Kind-hearted, generous, and a true sportsman, he will be sadly missed by all who knew him. He was a born journalist, a brilliant writer, and a hard worker, and the more work he had to do the more cheery he became. His active work with our parent journal *The Autocar* ceased in the spring of 1915, after which time Mr. Swindley suffered from a sad and long illness, which terminated in his death on the 14th inst.



NOT A POST-WAR MODEL.

A motor cycle made at home by a Toronto rider from various pieces saved from the scrap heap. The machine is made up of two odd bicycle wheels, some salvaged bicycle parts, water pipe, reconstructed two-stroke engine, portion of a piano stool, coal oil tin, and odds and ends of tinware, chains, and leather. This one and only model was produced without drawings or sketches of any kind. Absolutely the only new parts about the machine are the head lamp and horn.

Petrol Economy in U.S.A.

In order to bring about petrol economy without disturbing transport interests, the U.S. Government has agreed to encourage the manufacture of electric lorries for use in America, and for export to this country.

A Severe Blow.

It has recently been announced that the Government has decided not to proceed further with the Petroleum (Production) Bill.

The Exploitation of Home Fuel Supplies.

This announcement is certainly perturbing to the motorist, but it has since been explained away. The Bill has been dropped so that the King might issue an Order in Council to the same effect.

The Order in Council is, of course, much more easily and rapidly brought into being, and the Government has just discovered that new legislation, as such, is unnecessary.

Potatoes for Alcohol.

Most of our readers will be aware that for many years we have had frequent discussions in our columns on the use of alcohol as a petrol substitute, and on the possibilities of producing alcohol from home sources. This latter matter has now reached Parliament at last, and Mr. Clynes said something in answer to a question which could mean that the Government were keenly interested in the production of alcohol from potatoes or that they were simply pretending to show interest to save themselves from further agitation and bother.

Putting the most charitable interpretation on this excellent specimen of spoken official jargon, it meant that the Government were considering the advisability of experimenting on potatoes unfit for human consumption! Truly a mighty and difficult question for a Government official or department to have to tackle, though the ordinary man might be so lacking in acumen that the question would appear comparatively easy of answer.

Alcohol as Fuel.

This fuel question is one that ought by now to have been recognised as having passed joking limits, and it is sad to find that this is not the case. Alcohol can be made from potatoes, unfit for human consumption, at about 3d. per gallon, and it can be used as an excellent fuel in a suitably-designed engine.

But it is prohibitive in its cost on account of Excise restrictions—no maker can be expected to turn his attention to an engine that will use a fuel already taxed something like 1,000% *ad valorem*, and this without being recognised as a motor fuel!

The time will come when alcohol will be widely used, so why cannot we get on with the preparations now?

AMERICAN AND BRITISH MACHINES.

A Candid Opinion, not Altogether Favourable to American Methods.

THERE are one or two points on which the popular type of American machine scores over the British, but there are many on which it loses. The American has still a long way to go ere it is anywhere near the Britisher for accessibility. To give a single instance—two machines recently adorned my garage, one a 3½ h.p. British-made flat twin, and the other a 40° Yank. To remove the magneto from the flat twin merely necessitated loosening off two nuts, when the magneto slid clean out, together with its one-way dog, but to remove the magneto from the American is a matter of two good hours' fiddling and knuckle barking, removing of exhaust pipes and wangling of engine plates, while restoring it is on a par with the work of taming an African hyena.

To take a further example, the removal of the pilot jet on my present American twin necessitates removing the whole carburetter unit, complete with the induction pipes, as the pilot is inaccessible till this is done.

Engine Vibration.

The Americans certainly have beaten us on what might wrongly be described as sweet running, *i.e.*, an engine which ticks along with a minimum of fuss. The tappet mechanism and valves are lighter than in most British twins, a good deal quieter in operation, and the silencing is uniformly good. But it is merely the quiet valve mechanism and the good silencing which conveys that impression of sweetness. One or two American engines are well balanced, but others possess a most appalling period, and, taking all with all, the British twins are better balanced.

Probably the only reason why there are riders who praise the Yank at the expense of the British is because the Americans produce a type of machine which has no exact counterpart over here, *i.e.*, the high-powered chain-driven twin, light enough to use as a solo mount. The man who fancies a light and powerful solo twin really cut out for solo work has practically no alternative but to buy the Yank, and since it gives him perfect satisfaction he sings its praises. And the more narrow his experience the louder he sings, resorting, probably, to comparisons founded on paper "experience."

Detail Finish.

On American machines there are fittings and fittings, many of which would not be tolerated for one moment from a British factory. Their motor cycle brakes are certainly superior to their car brakes, and generally work well, though it is a marvel to me how the detail parts of many American machines ever hold together. Very often the detail finish is too appalling for words, the brake parts particularly being reminiscent of a village smithy, yet somehow they seem to hold together till permanently rusted on the frame.

I have no quarrel whatever with the twist grip, except that I regard it as an incentive to bad driving, for one does not obtain that nicety of adjustment given by handle-bar levers. In traffic, for instance, when ticking along on the pilot, one's natural impulse on seeing an opening is to give the twist grip half a turn, thus banging the throttle open to an extent one would not dream of with handle-bar controls. The twist grip throttle control has three positions in ordinary use—pilot, half throttle, and full throttle—no other stages being recognised by the rider, so that his petrol consumption is generally high. The twist grip for the exhaust valve and ignition is excellent, for here no particular delicacy is required.

Multitudinous Small Parts.

The design of many American machines is excellent, but the details——! For instance, one is led to wonder whether one highly-paid individual is appointed to supervise the distribution of split pins. There are approximately sixty split pins holding together the more or less vital parts of my present American, and I should not like to think that the distribution of these minute, spiky, yet vital units had been undertaken by any but a trustworthy and conscientious mechanic. Of course, their occasional use is advisable, but though the split pin makes a very simple way of fastening, one cannot help but regard its wholesale use as savouring of agricultural machinery and lawn mower practice.

One appreciates the little points of thoughtfulness and convenience in American machines, but in the opinion of one rider, at any rate, the average Yank is nowhere in the same street as the average Britisher as an engineering job.

I am not attacking American systems for the fun of the thing or with any ill-feeling towards them, but simply because many unfair comparisons have been made by people who have not sufficient knowledge of both products to express an accurate view. I consider that such machines as the Harley-Davidson, Henderson, Indian, and one or two others are beautiful mounts—far ahead of us on many points, but equally behind us in others. What appals me most on one or two American makes is the way the frames are drilled at the very weakest and most vital points, and with an apparent lack of thoughtfulness. Often holes are drilled in the *bends* of the chain stays or rear forks to take some trivial fitting, such as a chain-guard lug or a carrier stay, and thus the whole strength of the rear structure is jeopardised. It is surprising that designers who exhibit such care and forethought in many directions should fall short of what practically amounts to commonsense in such details as this.

CHINOOK.

THE DOUGLAS FOR 1918.

New Models of a Machine Very Popular both in Military and Civil Circles.

Practically no Striking Innovations are made, but there are Several Small Refinements and Improvements.

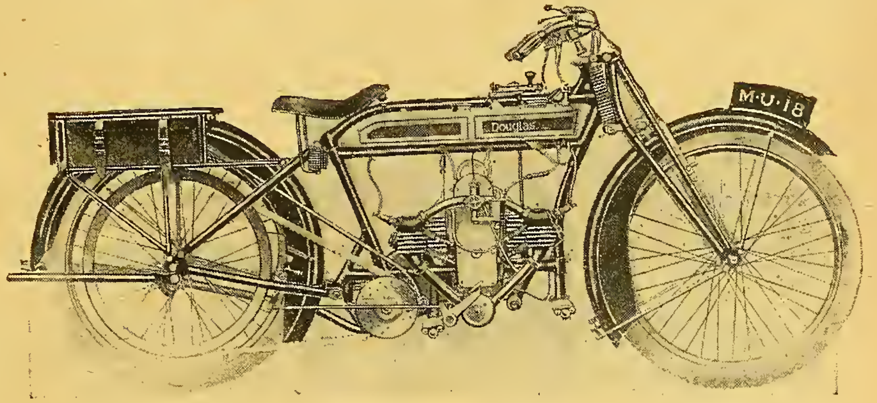
ALL motor cyclists know how well the Douglas has served the country during the present crisis, and after the war there is no doubt that when it is again available to the general public it will be found to have been vastly improved. The following are some details of the 1918 models:

That most popular model, the 2¾ h.p., which brought the house of Douglas into such high repute, is the leading line, and is being made in two types—models W and V. The 1918 model W, is to be equipped with a three-speed gear, handle-bar-controlled clutch, kick starter, footboards, and Tourist handle-bars, and is marketed at £65, including the 20% war advance. The Tourist type handle-bars fitted are much lower than the usual pattern, but, being in comparison with the saddle, much higher than previously, the former amount of comfort is retained, and the rider has an additional amount of controllability over the machine. These handle-bars are fitted to both models W and V, which are the only two diamond frame 2¾ h.p. Douglas machines listed for the present year.

The new Douglas spring forks. The links are now in one piece with the spindles, and means of adjustment for taking up wear are provided. Note also the ample mudguard clearance.

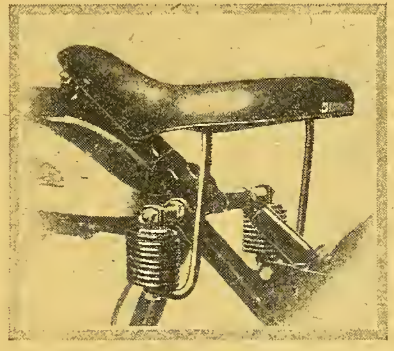
The V type is the popular T.T. model, and is now fitted with footrests, a three-speed gear box without clutch, and an adjustable pulley. It is sold at £55, including the 20% war advance.

A commendable feature is that adjustable pulleys are fitted as a standard to all 1918 models.



The 1918 Model V Douglas. There are no startling innovations or departures from previous designs, but the fitting of a hot air jacket for the carburetter is an interesting feature. The pipe conducting the heat from the front exhaust pipe is clearly shown in the above illustration.

The frames are now constructed in such a manner that the post-war rear springing may be attached at any time.



The new Douglas saddle arrangement used on both the 2¾ h.p. models (W and V). A low saddle position is obtained in combination with a normal driving position and semi-T.T. handle-bars.

Mention has been made above of the new saddle position. The saddle is a Lycett la Grande, the peak of which is pivoted directly on to the top tube, while the springs are anchored to an extension of the usual seat lug bolt.

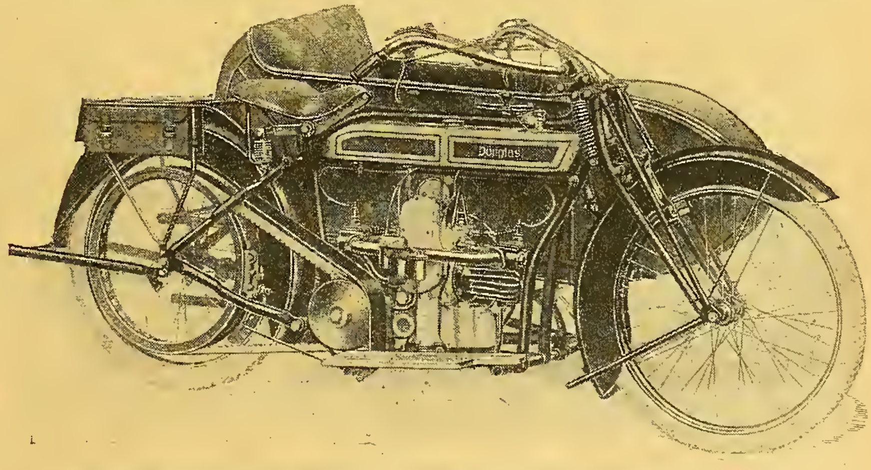
As regards the engine, the usual swivel type of exhaust pipe has been replaced by pipes giving a better clearance and leading directly into the silencer expansion chamber, so that the exhaust gases from one cylinder do not impede those from the other.

Warming the Carburetter.

The new tank is of exceptionally pleasing appearance, tapering as it does towards the rear, and having rounded edges. The excellent metal protected toolbag of large capacity, which met with our approval when we last inspected the W.D. model at the company's works, has been retained.

It is interesting to note that the carburetter warming jacket is connected to the front exhaust pipe, which, being freer from oil than the rear exhaust pipe, does not tend to choke the jacket with soot. Wide mudguards with ample clearances and chain and belt guards are fitted to all models. Dust covers of pressed steel are fitted to the adjustable tappets to prevent dust and grit from entering the guides.

The model X machine, which is listed at £65, is intended for ladies. It is now fitted with a handle-bar controlled clutch,



The 1918 Douglas 4 h.p. combination. This has undergone practically no change, and is available against a Ministry of Munitions certificate.

Douglas Machines for 1918.—

three-speed gear box, and kick starter, and is similarly equipped to the models we have previously described.

A great improvement has been made in the design of the 1918 front forks, which are now provided with links in one piece with the spindles, and are supplied with a means of adjustment for taking up side play or wear. The wide mudguard clearance can be clearly seen in the photograph. Large grease cups are provided to all fork bearings. This type of fork is standard to all the machines.

The 4 h.p. model A, which is provided with a three-speed gear box but no clutch or kick-starter, though it has an adjustable pulley, T.T. handle-bars, and footrests, has undergone no alterations except the fitting of round front down tubes instead of the D section. This type is listed at £70.

The Sidecar Machine.

The model B 4 h.p. Douglas is the sidecar machine sold at £92 10s. This also has undergone practically no alteration from the previous model. It is fitted with mechanical oiling, Amac carburetter (though a Douglas is shown in the illustration), three speed gear box, foot-controlled clutch, adjustable pulley, and footboards. The coachbuilt sidecar is finished in green and upholstered in red. This model can be delivered immediately to farmers, munition workers, doctors, and those concerned in the supply of food, on obtaining a priority certificate from the Ministry of Munitions. As those motor cyclists who can obtain priority certificates will doubtless be in a position to obtain petrol also, we should imagine that many will be glad these models are available.

* * *

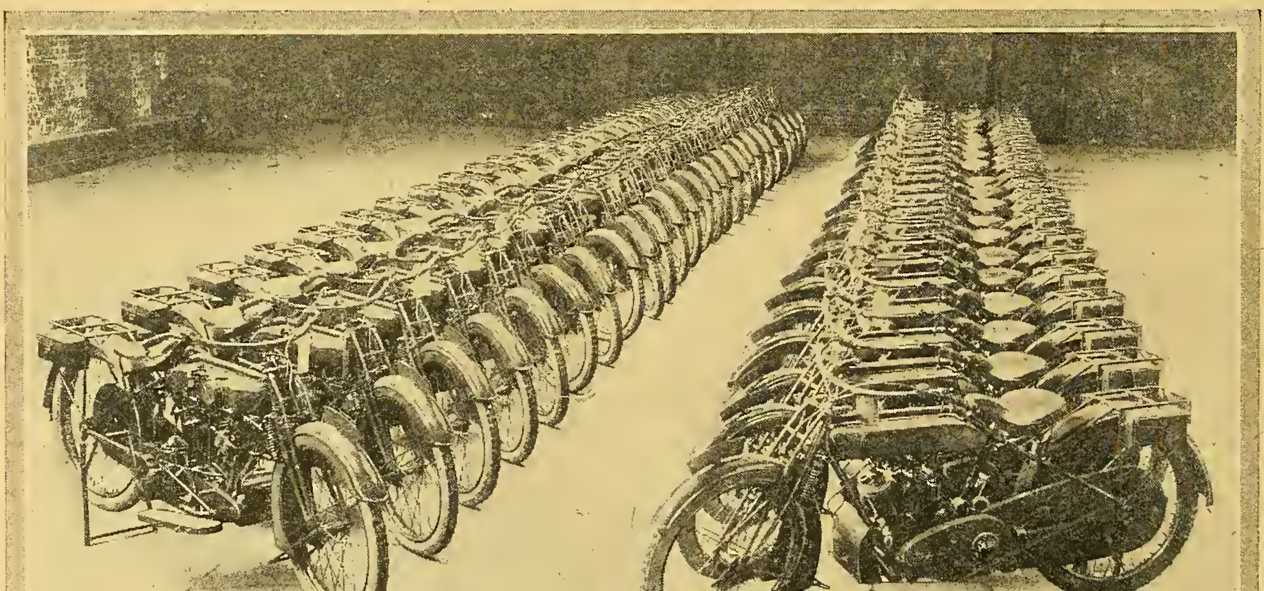
HELPING U.S.A. ARMY MOTOR CYCLISTS.

How American Commercial Methods are being introduced into the Army.

As an example of what American manufacturers are doing to render the use of the motor cycle entirely satisfactory in the United States Army, we are able to quote a few facts gleaned from information received from Mr. Walter Davidson, of the Harley-Davidson Motor Co. In the United States the company has fifteen or sixteen men belonging to the factory visiting the various cantonments, and doing nothing but setting up the machines and then instructing the riders how to handle them. These cantonments are practically new cities built up in various parts of the country, and, of course, with no facilities for repairing the various motor cycles which are in use in them, so the Harley-Davidson men had a big job in front of them. The company has now one of its own men, a very good organiser, going from camp to camp, and taking up with the various commanders the question of organising repair corps inside the camps, and also giving all possible incidental assistance.

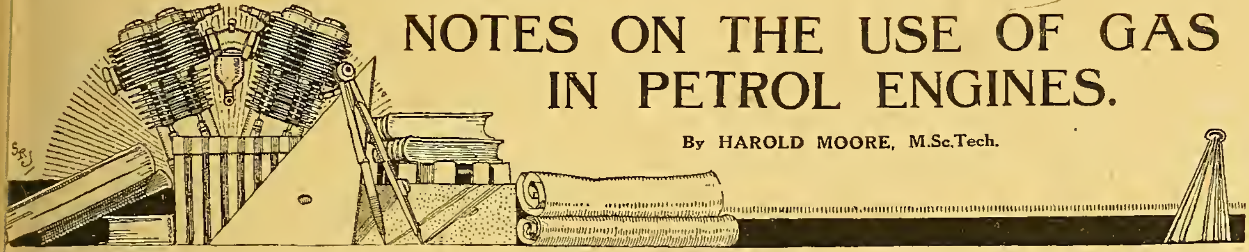
Mr. Walter Davidson writes: "I am sure that when we get through with this work the Army will have reduced the repairing of motor cycles to a science, and the result will be that, instead of having a number of broken-up and 'joy-ridden' motor cycles to damage the reputation of this type of vehicle, they will have highly efficient mechanics taking care of these machines, so that they may give 100% efficiency. The motor cycle is gradually being recognised in the United States Army as a very essential instrument of warfare, and it is our duty to hasten its recognition as fast as possible.

"The United States Army intend to carry a supply of spare parts equivalent to a typical factory stock, and they intend to carry a stock at each one of the cantonments in the U.S.A. You can readily appreciate that this has been an immense task, as the Army had made no provision for taking care of the machines they had bought. When I tell you that they are taking over seventy-five of the very best motor cycle repair men that we can find for service in the base repair shops in France, you will realise that they are going after it with the proper spirit. These repair shops are going to be immense institutions employing thousands of men, and equipped with every kind of machinery imaginable. We here in the factory are going to supply the necessary parts to take care of the machines, and are also working on all the repair tools which they will need to salvage the motor cycle in every respect."



ROVER MOTOR CYCLES FOR THE AMERICAN ARMY.

A consignment of military model Rover motor bicycles recently supplied for the use of the American Army in France. The machines are the latest model 5-6 h.p. Rover, fitted with J.A.P. engine, 28in. × 3in. Dunlop tyres, all-chain driven, with both chains enclosed, and a three-speed countershaft gear. One of the chief points of interest in the design is that the crank cases have a 6½in. clearance. The Government has given the New Rover Cycle Company permission to dispose of a few of these machines for private use.



NOTES ON THE USE OF GAS IN PETROL ENGINES.

By HAROLD MOORE, M.Sc.Tech.

The following article provides a *résumé* of most of our available knowledge on the use of coal gas, and also briefly indicates one or two points in its use as a motor fuel that should be new to most of our readers. The author of the present article supplied most of the information published in the article on "Spontaneous Ignition," by P. J. M., in our issue of December 13th, 1917. The problems involved in carrying the gas have been purposely overlooked, as they have been dealt with so fully in several of our recent issues.

THE use of gas in petrol engines has come as something in the nature of a surprise to the motoring public, and as a testimony to the ruth of the old adage concerning the relationship between necessity and invention. As a temporary substitute for petrol, gas has already taken a prominent position, and the writer does not propose to deal with its use as a temporary fuel, but to consider its possibilities as a permanent substitute for the liquid fuels hitherto used in petrol engines.

The points that have to be taken into consideration when valuing the respective merits of gas and petrol may be classified under three headings:

(1.) Price, quantity, and quality of gases available.

(2.) Mechanical problems regarding storage, charging of containers, design of carburetter, etc.

(3.) The scientific problems encountered in burning gas mixtures.

We will examine in turn the more important factors which can be placed in these three main categories.

Price, Available Supplies, and Qualities of Gas.

It is necessary to take into consideration the price of our ordinary motor spirits in order to make a comparison of the economy of their use and that of the use of gaseous fuels. The present prices of petrol cannot be considered as in any way a measure of post-war prices. War requirements and shortage of transport facilities have increased the demand whilst diminishing the supply. High insurance premiums have also contributed to raise the prices. Pre-war prices of petrol and shale spirit may be taken as 1s. to 1s. 6d. per gallon retail, with approximately the same prices for benzole, whilst heavier substitute fuels could be bought at 6d. to 1s. per gallon. After the war, when normal conditions are approximately restored, we may expect the following influences to affect the price of motor spirit. There will be an increased consumption on account of the natural increase in motor traffic, and a new demand for aircraft used for purposes of business and pleasure, while probably there will be a decreased Government demand. It is, however, certain that the total requirements will be greater than ever before. The supply of petrol will be vastly increased, this increase being due to three main causes: Firstly, the enormous amount of spirit produced from heavy petroleum oils by the new "cracking" processes; secondly, the increase in the supply of benzole brought about during the war by Government regulations, and largely due to the "stripping" of benzole from coal gas, a process which has been made possible by relaxations in the standard requirements in illuminating power of coal gas supplied in towns; and, thirdly, because the war time experiences in running on heavy fuels will have brought many products within the range of motor users which before the war were considered unsuitable for use in petrol engines. To estimate the effect of these conflicting influences, together with many minor factors, is too complex a problem to allow of direct calculation, but the writer holds the opinion that the price of motor spirit (disregarding the influence of competition from gaseous fuels) is not likely to be much higher than in pre-war days. [We hope this optimistic opinion will prove to be correct, but we have our doubts.—ED.]

The price of gaseous fuel must first be reduced to a basis such as to allow of a direct comparison of price with liquid motor spirits.

Several authorities have stated that 250 cubic feet of coal gas will propel a motor vehicle the same distance as one gallon of petrol, a value which is in sufficiently close accordance with results obtained by purely theoretical calculation.

Comparative Prices of Gas and Petrol.

Coal gas from towns' supplies costs 2s. to 4s. per 1,000 cubic feet when bought for domestic purposes, and in many towns a large profit is made by selling it at these prices. A large part of the cost of gas is due to the upkeep and capital charges on the distribution and meter system outside the gas works. If supplied at pre-war rates charged for industrial purposes the price should be about 2s. per thousand cubic feet, which is equivalent to petrol at 6½d. per gallon.

Gaseous fuel is obtainable from other sources than gasworks plants. It is produced in enormous quantities as a by-product from coke ovens and blast furnaces, and can be prepared in water gas plants, gas producers, and oil gas plants. The gas obtained from water gas plants, producers, and blast furnaces is considerably lower in heat value than coal gas, and the use of such gas would greatly decrease the mileage obtainable on a motor vehicle from a container of any given capacity. This would probably exclude these gases from use as motor fuels. As oil gas is prepared from heavy petroleum oil its cost is dependent upon the price of petroleum (a very variable figure). Coke oven gas is obtained as a by-product in the preparation

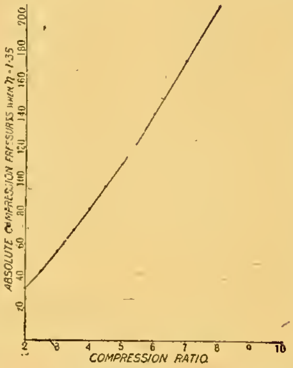
Notes on the Use of Gas in Petrol Engines.—

of the coke used for metallurgical purposes. The price of coke oven gas depends largely on the locality of the coke ovens. It has generally about the same heat value as gasworks gas, and is available at a much lower price than the latter product. It should be obtainable for motor purposes at a price below 1s. per thousand cubic feet, equivalent to petrol at 3d. per gallon.

From the foregoing it is evident that gas is much cheaper than petrol can possibly be, and that there is no doubt that, after the war, even if the taxes on petrol were abolished, gas would still be the cheaper fuel.

Many substitutes for petrol have been found in the past, but hitherto it has always been the case that as soon as a substitute came into use in quantity it rose in price until there was little or no advantage in using it. This phenomenon, of course, is due to the comparatively small amounts of substitute which have been available. It therefore presents itself as a question whether the use of gas in petrol engines will reduce the price of petrol or increase the price of gas. If sufficient gas can be prepared to cope with normal demands, and at the same time to supply the motor fuel market, it will not rise seriously in price.

The production of gasworks gas in the United Kingdom is about 200,000,000,000 cubic feet per annum, whilst the quantity of gas generated in coke ovens cannot be much short of this figure. A considerable proportion of the coke oven gas is, however, used for heating the coking chambers, and would therefore have to be deducted in order to find the quantity available. The motor spirit imported into this country during 1914 was approximately 120,000,000 gallons, which, together with shale spirit and benzole, would make roughly 150,000,000 gallons of spirit available for motor use. This is equivalent to about 30,000,000,000 cubic feet of gas, or 15% of our coal gas output. The production of this extra quantity of gas would undoubtedly necessitate an increase of plant, but it would be in no respects impossible to produce the extra amount, and thus completely supply the motor market.



ATMOSPHERIC PRESSURE P_a = 12·5 LBS. SQ. IN n = 1·35	ε =	2·0	2·5	3·0	3·5	4·0	4·5	5·0	6·0	7·0	8·0
	p_c =	31·9	43·0	55·1	67·8	81·2	95·2	109·5	140·5	162·4	206·5

The absolute compression pressures produced by various compression ratios.

The Question of Enriching Coal Gas with Acetylene.

It has been suggested that the addition of acetylene to coal gas would increase its heat value. At the present time there would be the greatest difficulty in obtaining either acetylene or calcium carbide in large quantities, and even if prices were to fall to pre-war standards acetylene would still be too expensive for use as a motor fuel. It may also be remarked that it possesses a lower temperature of spontaneous ignition than coal gas, and would therefore reduce the maximum compression permissible. The comparatively high carbon and low hydrogen content of acetylene, together with its chemical structure, creates a danger of the deposition of carbon inside the engine if large percentages of this substance be employed. The heat value of acetylene is much greater per unit of volume than that of coal gas, one cubic foot yielding 1,500 B.Th.U. net: a similar amount of coal gas yielding only 500 B.Th.U. Thus gas could be available in sufficient quantity to replace petrol, and at about one-tenth the present price of this fuel.

The Scientific Problems encountered in using Gas as a Motor Fuel.

When a fuel mixture is compressed in an engine it becomes heated, the temperature obtained at various pressures being shown below:

Gauge pressure.	Temperature.
0 lb.	30° C. (assumed temperature of charge on entering cylinder)
15 lb.	103° C.
30 lb.	133° C.
45 lb.	162° C.
60 lb.	186° C.
75 lb.	207° C.
105 lb.	242° C.
135 lb.	271° C.

Now if petrol be heated to 270° C. in an enclosed vessel under conditions approaching as closely to those of an engine cylinder as are obtainable under laboratory conditions, it is found that at that temperature the petrol will ignite spontaneously (without any spark). Therefore if our compression be over 135 lb. per square inch it will cause the charge to ignite before the occurrence of the spark, and "pre-ignition" or early firing will take place even when the engine is cool. With a hot engine with highly heated exhaust valve head and sparking plug points this pre-ignition would take place at a much lower pressure than 135 lb. per square inch; in fact, we find that about 90 lb. per square inch is as high a pressure as is practicable on an engine required for general use. Though this applies to petrol it does not follow that such a compression should be the limit for ordinary use on other fuels, the compression pressure allowable being dependent on the spontaneous ignition temperature of the fuel. The writer published the results of the experimental determination of the ignition points of several liquid fuels in *The Motor Cycle* of December 13th.

It will be observed that petrols ignite at about 270° C. Paraffin oil is considerably lower in ignition point, which accounts for the knock and overheating (both due to pre-ignition) that are frequently noticed when running high compression engines on this fuel. Motorists who have run on benzole will know that it does not readily pre-ignite.

The ignition point of coal gas is over 500° C., which means that the compression can be considerably raised without danger of pre-ignition. On gas engines running on coal gas compression pressures as high as 180 lb. to 200 lb. per square inch may be employed.

The thermal efficiency of an engine is dependent upon the compression ratio, and a great saving in fuel can be accomplished by raising compression wherever possible. The theoretical thermal efficiencies for

Notes on the Use of Gas in Petrol Engines.—various compression ratios are shown in the accompanying graph (see fig. 2). In practice efficiencies are considerably below theory, and we find that a compression of 70 lb. (on a high speed engine) yields about 20% efficiency, 120 lb. yields about 28%, and 200 lb. per square inch yields over 32% thermal efficiency. If the compression of an engine be raised (by lengthening the connecting rod or piston head) it will not run satisfactorily, however, on fuel of low ignition point, therefore before raising compressions we must decide whether we wish to run on gas at all times.

Increased compression also greatly increases the power output of the engine, and if raised compressions were adopted for running on gas the complaint of decrease of available power would be remedied. From the foregoing it is evident that the results obtainable from gas can be greatly increased by raising the compression of the engine if it is not required to use the engine on other fuels. The increase in both power and efficiency would be in the neighbourhood of 25%, and would increase the mileage obtainable from a container of any given capacity by a corresponding amount.

The effect of the gas upon the lubrication system would not be so deleterious as that of liquid fuels, as there is no possibility of gas becoming dissolved in the lubricating oil, as is the case with ordinary motor spirits, and the deposition of carbon in the cylinder is not so likely to occur with gaseous as with liquid fuels. The "petroil" system of lubrication for two-stroke engines would have to be abandoned, of course.

The "flexibility" of an internal combustion engine is largely dependent upon the explosive range of the fuel. The mixture of petrol vapour and air at ordinary pressure is not explosive (according to Eitner) unless the content of petrol vapour is at least 2.4% (by volume), and not if it be in excess of 4.9%. These limits do not directly apply to internal combustion engines, as the charge in an engine is under pressure at the time of firing; they, however, form a rough measure of the probability of engine stoppage due to the mixture becoming either too weak or too rich to explode. With coal gas the explosive range, according to the same authority, is 7.9% to 19.1%, a considerably wider variation of mixture being permissible than when burning petrol. Thus coal gas, if the running be properly controlled, should prove a much more flexible fuel than petrol.

In conclusion, the possibility that gas may become a really serious rival to petrol depends upon many factors, the more important of which we will briefly summarise:

(1.) Coal gas can be prepared in the United Kingdom in sufficient quantity for all present motor purposes by increasing the number or size of carbonising plants in the country.

(2.) The price of gas will make it a much cheaper fuel than petrol is ever likely to be.

(3.) The storage of gas at atmospheric pressure is satisfactory for short distance travelling.

(4.) High pressure systems will require compressors, and will therefore be more expensive. They are more convenient; adequate for longer journeys, but require experimental work before they can be suitable for general adoption.

(5.) Dissolving coal gas in some other body, in order to lessen the necessary volume of the container, presents serious difficulties, but might be done after the necessary research work.

(6.) Gas, if passed through a suitable carburetter, should start an engine very easily.

(7.) If gas be used in special engines with raised compression, much higher thermal efficiency and better mileage will be available.

(8.) Gas is a much more "flexible" fuel than petrol.

* * *

GASOLINE AND GAS IN AMERICA.

We have several times in these pages chaffed our American cousins for calling petrol "gasoline" for short. Gasoline is obviously much too long a word in the land of abbreviations, so they usually speak of it as "gas," with what confusion can be judged from the paragraph given below, which was taken from an American journal:

"Whether gasoline is gas or 'gas' is to be decided in the courts of Pennsylvania, and may from there go to the United States Supreme Court. According to the United Natural Gas Co., gasoline is gas, and when it is removed from natural gas, to make it 'gas,' the removal deprives the buyer of the natural gas of gas that he has ordered and will in due time pay for. The Alum Rock Gas Co., of Franklin, Pa., which has been selling 'gas'-less gas to the United Co., says that gasoline is 'gas,' not gas, and that it does not intend to furnish both gas and 'gas' when its contract calls for only gas. Since the suit concerns the ownership of the 'gas' in gas, and is the first of its kind, it will be pushed to a complete adjudication."

Now we know all about it.

The Autocar says: "We shall not be surprised to see the Board of Trade come out with an announcement in the near future that until further notice no motor spirit imported from Overseas shall be disposed of to the public at a higher price than a figure to be mentioned in the announcement."

MILITARY NOTES

TYPE OF MAN FOR FLYING: ONE OF THE "ORIGINALS."

PROMOTION OF BREVET-COL. E. D. SWINTON.

BREVET-COL. E. D. SWINTON, C.B., D.S.O., R.E., is to be promoted temporary major-general while engaged on special work. In 1911 Gen. Swinton, then major, was one of the observers on a German car during the Prince Henry Tour. He was also partly responsible for the introduction of the Tanks. Gen. Swinton is the author from whose pen emanated "The Green Curve," a book which caused a sensation prior to and during the beginning of the war.

* * *

M.T. IN THE FIGHTING ZONE.

A COLONEL in the Gunners, who is a keen motor cyclist, writes: "I have been amused at a letter regarding the risks run (or said not to be run) by the A.S.C., M.T., men. As a matter of solid fact, they do have a jolly rotten time of it. Very often they have to carry out extremely dangerous jobs in cold blood. They are thoroughly deserving of all the praise they may get, and they often do not get half enough of it for what they have to go through." Referring to the letters on the subject, the colonel states:—"Some of them are certainly the effusions of people who do not frequent the region of the front line."

LADY MOTOR CYCLIST TRANSFERRED.

Miss Mary Reid, of Aberdeen, a pioneer Scottish lady rider, who joined the R.F.C. as a despatch rider, is now in France. She has been transferred to the W.A.A.C., and is at present driving a "Prince Henry" Vauxhall. Miss Reid drove a Brough in the last Scottish six days' trials.

MR. LLOYD GEORGE ON THE AIR SERVICE.

MR. LLOYD GEORGE, in the course of a recent speech, remarked that the operations of the Air Service will probably have greater effect in determining that this must be the last war than any other weapons.

Sir Frederick Smith, in proposing the health and prosperity of the Air Service, said that it might well be that in the next twelve months the future of the war would be determined by the conquest of the air. That could only be if there were harmony and co-ordination among all those who were mastering the enemy in the air. If there were competition between the Army and Navy, and a third element of competition by some neutral, or hermaphrodite board, it was evident that there never could be success, and his appeal to them was that there should be no controversy between the Army and Navy.

* * *

TYPE OF MAN FOR FLYING.

CLARENCE WINCHESTER, author of "Flying Men and their Machines," writing in the *Daily Mail* recently, dwelt on the question of the type of man best suited for the making of an airman. He said: "There is no general rule as to the characteristics to be found in a good pilot, but I can safely say that to possess 'hands' is very important in actual flying.

"I have had very promising pupils deteriorate at the end of a course. I have seen slow-moving landsmen become quick-witted and alert airmen, and I have known men very quick on the ground to be too slow in the air—with the resultant crash! The ambition of one embryo pilot I knew was to become a church organist, and when he was not on the flying ground he was practising on the parish church organ. Another, before learning to fly, was a grocer's assistant; and this leads me to express the hope that in the new Air Force provision will be made for all ranks to learn to fly instead of confining this privilege almost exclusively to the officer class.

"There is one warning I would give to parents whose sons may be anxious to fly. If they intend their boys to remain in aeronautics professionally after the war, they should see that they are equipped with a knowledge of engineering and aeroplane design, for the mere ability to pilot aircraft will be so common that aviators will be cheap."

* * *

AIRMEN'S CONVALESCENT HOME.

A CONVALESCENT home for flying officers in the R.F.C., entitled the R.F.C. Auxiliary Hospital, Overseas Club Branch, has been opened near Croydon, at Shirley Park, which affords many facilities for outdoor recreation.

Every room or ward in the home will be named after some part of the British Empire, or some British community in a foreign country, which is contributing towards its upkeep.

* * *

ONE OF THE "ORIGINALS."

GNR. "BILLY" RENNISON, Tank Corps, who was severely wounded in the "Byng push" at Cambrai, is now in hospital at Etretat, France. Gnr. Rennison is one of the few remaining of the famous C Company of the Motor Machine Guns—those gallant lads who took the first Tanks into action in the autumn of 1916. He has taken part in every "push" in which the Tanks have figured, and still pins his faith to the old "'buses," for, now that he is wounded and out of action, he has sent home his savings to be invested in the Tank Bank. Prior to the war, he was a well-known North-country motor cyclist, and for some time acted as despatch rider at the Tank Headquarters.

Gunner "Billy" Rennison, Tank Corps.

LETTERS to the EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

REQUEST.

Sir,—May I appeal through your columns to your readers or the loan of a catalogue and illustrations of the Singer motor cycle, 1903 (?) model, with engine in wheel? The makers are quite out of all printed matter of this machine; hence my request. (Rev.) JOHN HODGKIN.

Whittington-in-Lonsdale, Carnforth.

ENGINE BALANCE.

Sir,—I would respectfully suggest to "Nortonian" that he should go carefully over his engine holding bolts, and see that they are all absolutely tight. Unless his engine has been in the hands of some of our war-time "motor engineers," and alterations from standard made, or the engine itself is loose in the frame, I cannot understand his trouble, as I know of no better balanced single-cylinder engine. At 60 m.p.h. the 79×100 engine is almost as effortless as the average flat twin. M.B.

Ystalyfera.

FRONT WHEEL BRAKES.

Sir,—I have often seen in your columns comments on "Useless Front Wheel Brakes." Why does some manufacturer not employ the internal expanding brake drum on the left side of the front wheel, and operate it by the usual Bowden wire? The wheel could still be detachable and interchangeable on the A.J.S. principle.

The dummy belt rim is all right for machines without detachable wheels, but when these are incorporated this type of brake is impracticable.

Although only sixteen and a half years old, I follow your interesting journal every week. I drove our 6 h.p. Ariel outfit from 1915 until the Petrol Restriction Order came in. F. R. ROYSTON.

TECHNICAL INACCURACY.

Sir,—In reference to the story by Angelina Simpkins, which appeared in your issue of December 20th last, and entitled "A Race with Ruin," may I say that the absurdity of several of her statements, undoubtedly, appealed to the commonsense of some readers, but they, like myself, took the article as a story, and saw the humorous side of it?

However, the statement made by Mrs. Simpkins that her conclusions were "based on complicated mathematical calculations" is so obviously a deviation from the truth that it should not be allowed to pass without comment.

The R.F.C. friend, of whom the lady speaks, does not show a perfect knowledge of motor cycles.

I sincerely hope that, if he ever becomes a pilot, he will not try to "oil the tyres" or "grind in the valves" whilst his engine is running. LLETTAC.

Rochdale.

Sir,—There are one or two letters in your issue of January 3rd which positively astonish me. I feel truly sorry for "Old Reader." All his sense of humour seems to have died out. Mrs. Angelina Simpkins is to be congratulated on having produced such an amusing story. "Old Reader" might try grinding in his valves at speed if he has got a hydrostatic turbine!

Such letters as those from Chas. S. Ives, F. Jones, and "R.O.W." are merely disgusting. If you begin to run short of readers some of us will have to take several copies per week.

I do not think anybody will deny that *the* weak point of the W D. Triumph is the design of the front fork, which causes front wheel slip. As regards power, I do not think there is much wrong with a motor bicycle that will climb Cassel Hill on top (I mean the hill coming into Cassel from the St Omer direction).

I hope no more pro-German readers will show their heads. Perhaps "R.O.W." does not *compris* that the Bosch magneto hindered our own magneto trade, because makers fitted it, and there was consequently no demand for British magnetos.

H. St. V. ADDENBROOKE, Sec.-Lt. R.E.

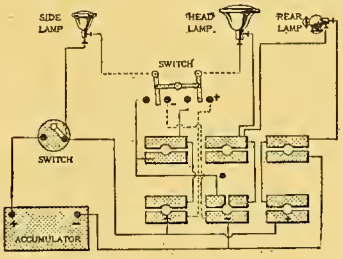
WIRING AN ACCUMULATOR LIGHTING SET.

Sir,—In reference to my solution of "Chinook's" accumulator wiring problem, I beg to draw your attention to an error that you have evidently made in printing. If you will refer to my diagram you will find that the wire connecting the head and tail lamps is earthed, and also the wire which is connected to terminal 2^1 of the switch.

By omitting the above the whole system is made unworkable. I shall be greatly obliged if you will call the attention of your readers to this in your next issue. C.E.S.

[We have looked up the original diagram sent us by "C.E.S.," and find that it coincides exactly with our artist's reproduction.—Ed.]

Sir,—In the many replies to "Chinook" *re* electric wiring I was somewhat surprised to notice that, apart from myself, none of your contributors allowed him to have his lamps in parallel should he desire to do so on very bad roads, etc. On the other hand, I arranged all my lights either in series or parallel, but should "Chinook" care to use my idea he can very easily use the head lamp in parallel and the other two in series by placing the plug top in the series plug and inserting a change-over switch in the head and side lamp wiring, and connecting according to the enclosed diagram, when by using only the change-over switch he can have either all lights in series or only the side and tail, or by placing the plug top in the lower plug he will have all lights in parallel. The change-over switches can be seen illustrated in any telephone list or are simple to make. C. A. COPINGER.



How the wiring may be arranged to give three different results.

EXHAUST POPPET VALVE DESIGN.

Sir,—Looked at with the eye of an ignorant amateur, all "Engro's" designs seem to have the objection that they expose a larger surface to the heat of the actual explosion than does the standard valve, consequently there would be great difficulty in lubricating the upper portion of the stems and guides. I very much doubt whether the hollow stem would counterbalance the larger amount of heat absorbed by the exposed stems. Nos. 4 and 5 have the further objection that the ends of the tappets are exposed to the hottest flow of escaping gases, and therefore would probably burr badly even if they were fitted with mushroom heads. The excrescence on the head of No 2 would be a grand source of pre-ignition unless very carefully designed, and it would make grinding-in a difficulty.

I think it is at least *optimistic* to talk of "cool" air being drawn through the valve. J. M. PHILPOTT.

CENTRIFUGAL FORCE.

Sir,—Your correspondent, "E.D.A." is right in controverting the theory of "Lieut. R.F.A." that centrifugal force acts tangentially; but his letter shows that he is not himself clear as to the meaning of this so-called force. The epithets "centripetal" and "contrifugal" must be allowed their proper meaning, otherwise the result will be only mental confusion. "E.D.A." has confounded the two. He calls that centrifugal (away from the centre) which is really centripetal (towards the centre) and *vice versâ.*

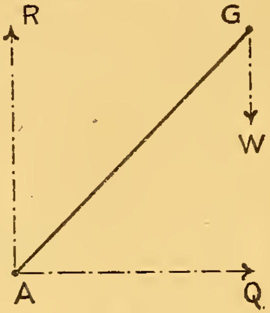


Fig. 1.

What is commonly called "centrifugal force" is not, strictly speaking, a *force* at all. It is, as "Lieut. R.F.A." rightly says, a fiction introduced to reduce a dynamical problem to a statical one.

To make the matter clear, we will treat the problem of a bicycle rounding a corner *ab initio.* It is a fundamental principle in dynamics that a body cannot change its state of rest or motion unless force be applied to it from outside. Thus, as Newton's first law of motion puts it: "A body if at rest remains at rest, and if in motion will move with uniform velocity in a straight line unless acted on by some impressed force."

Now, when a bicycle rounds a corner it is not moving in a straight line. Clearly then, there is some force acting on it that impels it to move in a curve, and if the bicycle is turning to the right it can only be because there is a force acting on it towards the right. This is the force that is rightly called "centripetal." It is a force directed to the centre of the circle in which we suppose the bicycle to be moving.

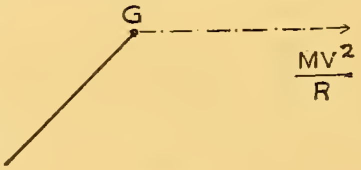

Fig. 2

Now we ask: Whence comes this force? A body cannot exert force on itself as a whole, though one part of a body may exert force on another part. The bicyclist cannot exert force on himself, but he can exert it, by means of his bicycle, on the ground, thereby causing the ground to react upon him—on the principle that action and reaction are equal and opposite.

What the bicyclist does then when he would move in a circle is (unconsciously it may be) to push against the ground with a horizontal force radially outwards. The ground responds with an equal and opposite force which is inwards. In fact, the ground supplies the centripetal force without which the bicycle could not possibly move in the circle. If the ground were perfectly smooth it could not create this force. And if the ground be rough, but not sufficiently rough to supply the needful force, a skid will result. It is a well-known fact that the force of friction that the ground is capable of exerting cannot exceed a certain quantity μR, where μ is called the coefficient of friction, and R is equal to the vertical pressure of the bicycle on the ground.

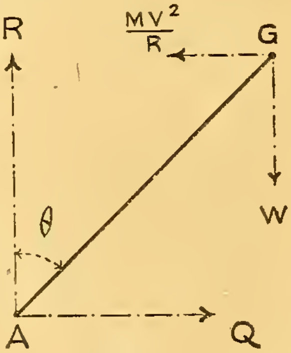

Fig. 3.

Let us suppose that the ground is sufficiently rough to allow of the bicycle's describing the arc of a circle, and let us suppose Q to be the force of friction exerted by the ground radially inwards. The forces acting on the bicycle and rider (regarded as one) may be expressed and calculated as follows:

W, their joint weight acting vertically through G, the centre of gravity.

R, the vertical reaction of the ground.

Q, the radial friction from the ground.

These forces will supply that which is necessary to make the bicycle move in the circle.

Now, in order that a body of mass m may move in a circle of radius r with velocity v, the force towards the centre must be $\frac{mv^2}{r}$. This is established in any text book of dynamics.

The centre of gravity of the whole bicycle and rider regarded as one will refuse to move in a circle unless the forces actually acting supply a force $\frac{mv^2}{r}$ through the centre of gravity and acting radially inwards.

The forces actually acting are R, Q, and W, as explained above. $\frac{mv^2}{r}$ is not a force actually acting. It represents what the forces acting must be equivalent to if the bicycle moves as it does.

As then the forces represented in fig. 1 are equivalent to $\frac{mv^2}{r}$, as shown in fig. 2, it is plain that forces, supposing them to exist as in fig. 3, would be in equilibrium.

Now it is this $\frac{mv^2}{r}$ (imagined acting radially *outwards* through G) to which the term centrifugal force is applied. But, as we see, it is not an *actual* force, so that the term is apt to mislead, and, as your correspondence shows, it has misled "Lieut. R.F.A."

Now as forces as shown in fig. 3 would be in equilibrium (note that we cannot say they *are* in equilibrium, for the $\frac{mv^2}{r}$ is non-existent as a force, and the bicycle and rider are not in equilibrium but moving in the circle), we must have by resolving vertically and horizontally

$$R = W$$

$$Q = \frac{mv^2}{r}$$

(which show that the vertical and horizontal forces form each a couple), and taking moments round A, the point of contact with the ground, we have, if θ be the inclination of AG to the vertical—

$$W \times AG \sin\theta = \frac{mv^2}{r} AG \cos\theta$$

$$\text{Whence } \tan\theta = \frac{mv^2}{rW}$$

and $W = mg$, so that

$$\tan\theta = \frac{v^2}{gr}$$

This gives the inclination of the bicycle to the vertical, and we see that for a given velocity the smaller r is the greater must θ be.

In conclusion, let it be understood that what is called centrifugal force is not really a force at all. It is a convenient fiction. It gives a measure of the tendency of the body to refuse to move in the circle; in other words, it is a kind of inertia.

MATHEMATICIAN.

Sir,—I think centrifugal forces play a part in keeping a bicycle upright, but I bring you here proof that the aid of these forces can be dispensed with. Many of your readers will remember some bicycle races which were held on music hall stages about twenty years ago. The machines were placed on four rollers—two for the hind wheel and two for the front one. One of the back rollers was connected with one of the front rollers, so that when the cyclist was pedalling the two wheels were spinning, but the bicycle did not move forward.

To start, the racers were held up by assistants, and after a few moments they were left standing alone and pedalling frantically, keeping perfect equilibrium.

It seems to me that the way of keeping the balance was only by leaning against the forces produced by the spinning of the wheels acting as gyroscopes.

ALLIED.

Davos-Platz.

FLYING FACTS AND THEORIES.

Sir,—I read with great interest Mr. Aston's article on "Flying Facts and Theories" in your issue of January 3rd. I am convinced, however, that he deals rather abruptly with "O.J.F.S." I am acquainted only with the practical side of aviation, and do not for a moment question Mr. Aston's ability in dealing with the technical side of the matter, but I would like to point out to him that it is quite possible to turn by the "feel" of the machine without referring to the various instruments on the dashboard. Indeed, in the R.F.C. it is the custom to impress upon pupils the necessity of flying as much as possible *without* using the instruments.

To get back to the point, however. In turning by "feel," the nose of the machine is kept just level with the horizon, and any deviation from this position is immediately corrected by means of the elevators. If the turn is correctly carried out (*i.e.*, correct proportion of rudder and bank), the pilot experiences a sensation of being pushed hard against the seat. If the machine is overbanked and sideslips inwards, a strong draught is felt on the side of the face, and the sickening "tube lift" feeling of dropping into space is experienced. If, however, the machine is underbanked and sideslips outwards (*i.e.*, a flat spin), a most unpleasant sensation results. All the surplus air in the neighbourhood appears to be forced up the nose and great pressure is felt on both sides of the head, seeming to push both sides of the head together. Naturally, when these incidents occur during a turn, the pilot is able to correct his errors.

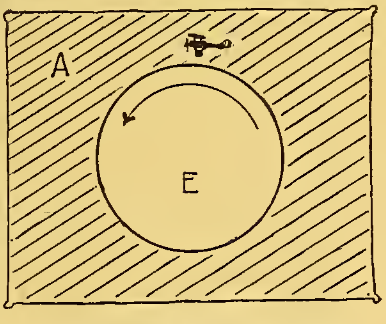
This may all seem irrelevant to the subject in question, namely, loss of height or speed in turning, but it is the outcome of a sentence in Mr. Aston's article which reads, "Next as to the 'feel' of the machine; this seems to be a singularly inexact method of doing things, and, after all, what *is* the 'feel' of the machine?"

I have tried, to the best of my poor ability, to answer this question. JACOBUS, R.F.C.

Sir,—As Mr. Aston's articles on "Flying Facts and Theories" may produce a further crop of letters from those who do not grasp the simplicity of the conditions governing the turning of an aeroplane "up" or "down" wind, may I save some of them from rushing into print by suggesting that they look at the matter in the following way.

Wind is a change in the relative positions of the air and the earth. Either of these can be considered as the stationary member, and the conception of flight in relation to wind is simplified by considering the air as stationary and the earth as in motion.

If A is the air and E the earth, the only connection between E and a body in A, not in contact with E, is gravity. As gravity is not affected by the rotation of E, this rotation can be ignored entirely until the body in A comes, or prepares to come, into contact, or is in danger of coming into contact, with E. W. J. LANGMAN.



A diagrammatic explanation of relative motion. (See letter from W. J. Langman.)

Sir,—Being a reader of your very excellent "Blue 'Un," I have taken a great deal of interest in the articles on flying by Mr. W. G. Aston, and also the letters of many critics.

It seems to me that if a body can turn (when not supported other than by the power of its engine) without losing height or putting extra energy forth, we must truly have arrived at a stage when man will be able to walk in mid-air.

A machine that is climbing may be able to turn, but in doing so it does not climb so fast as if it were travelling in a straight line, because in turning the altered position of the ailerons (I think that is the right name) causes a little more resistance to its rate of movement, therefore more power must be exerted to keep the same rate of motion.

In the turn when flying level, the machine will turn on its side a trifle, so causing less resistance to the air; consequently any unsupported body, by the laws of gravity, will commence to drop. To counteract this tendency to lose altitude, extra power must be exerted by the engine.

Would any of our pilots be so kind as to prove the argument in the course of their duties, as positive proof would be extremely useful? I think "O.J.F.S.," and "F.M.C.H." ought to try this, and then they may be convinced that weight needs support if it must retain its altitude. L.B., R.A.M.C.
(A Hopeful Pilot to be).

GOODS MADE IN GERMANY.

Sir,—Hearty congratulations on your attitude taken *re* goods "Hunnish." I shall take your paper as long as you continue to stand up for the "Right." I am never going to buy, or help the sale of, anything German!

St. Albans. TRIUMPH.

Sir,—Since I first wrote on the subject of Mr. C. S. Ives's communication you have received many other letters on this subject. With one or two exceptions they have all been in agreement, and rightly so. "R.O.W." talks about the German people being victims of Prussianism and nonsense of that kind. Mr. H. Leavis confesses to sharing the contemptuous irritation of Mr. Ives. Had he termed it "contemptible irritation" he would have been nearer the mark.

This is not, however, my object in writing this letter. What I really want to point out is this. I believe there is no doubt as to the authenticity of the German Corpse Factory. Many German goods, therefore, will in all probability contain products of this ghastly factory. It is not a pleasant thought, but that makes it none the less true. How anybody, knowing about this factory, can want to buy goods made in Germany, either after the war or at the present time, is to me incredible.

Here let me leave Mr. Ives and those who agree with him to enjoy in full the delicacies of the Corpse Factory, and I feel certain that British people will be only too glad to let them have their shares. C. A. HARRISON.

Sir,—I crave the liberty of your letters page to air my views regarding German-made goods, or, I should say, goods made in Germany, as there is no mention of goods made by a German if he be resident in England. It is to be hard luck for the German: he has heaped the trouble on his own back, and naturally deserves to suffer. I have no sympathy with him.

But what of the owners of German machines? There are many of them in this country, and they are mostly in the possession of enthusiasts who cannot afford to scrap them and buy new British or American-made machines. I think it is a mistake to insert the "Important Notice" week after week in *The Motor Cycle*. It is not in any other paper I have seen. The recommendation agreed upon at the Paris Economic Conference will never stand; it is like Chas. S. Ives's letter—an impulse of the moment. Our statesmen are beginning to see it is a mistake to shout about this trade war after the war. The latest is Mr. Lowther, Speaker of the House of Commons, at a war aims meeting at Carlisle on 29th December, who said *re* a trade boycott: It has been suggested that, whatever the terms of peace, we in Britain would have no dealings with Germany, and that we should boycott her commercially in combination with our Allies, and treat her as if she were a leper. He (Mr. Lowther) did not believe in that. If the recommendation passed at the Paris Conference is to stand it would simply be a means of carrying on the war; there would be the same hatred and the same struggle between one combination of nations and another—in fact, it would be in many respects almost as bad as the present war.

I am not so narrow-minded as to stop *The Motor Cycle* because of a notice appearing in it that I do not like; I can afford to wait a little, and no doubt the item referred to will disappear as quickly as it came. Wishing *The Motor Cycle* every success, J.S.B.

Woodside.

[*The Motor Cycle* and sister journals are now not the only papers to publish a notice of this nature.—ED.]

A SPORTING CHALLENGE.

Sir,—I notice Mr. S. A. Marks, in your issue of January 3rd, states he would be delighted to put his Model K Harley against any 8 h.p. J.A.P.-engined motor cycle, 85½×85. I have a motor cycle fitted with this engine, and shall be delighted to give him a run if he will kindly state under what conditions he wishes to run when circumstances allow.

Cardiff. A.C.

Sir,—In *The Motor Cycle* of December 20th I notice a letter from "Be Sportsmen" (Coventry), in which he states, in reference to the sporting challenge, that "every rider (obscure and otherwise) who has a machine he thinks can 'lick creation' is sending in challenges." Well, I have been at the game a few years—perhaps long enough to get past the "licking creation" stage—yet I have to suppose that I am one referred to, and probably as "obscure." The sum total of my letter is that I absolutely do not credit that a standard 85½×85 s.v. J.A.P.-engined machine can do over 70 m.p.h. as equipped at the time of the run.

Has "Be Sportsmen" not followed the papers and racing enough to know that the fastest km. on Brooklands with a light shell sidecar and stripped special machine stands at 72 m.p.h.?

I consider it was far more sporting to challenge the statement as I did, and back up my opinions by offering to match my machine on equal c.c. terms, than to make statements over a *nom de plume* totally unfitting and in direct contradiction to the tone of your correspondent's letter. Yet my letter and challenge have been ignored. I beg to assure "Be Sportsmen" that I shall, I hope, be one to help the frequency of these sporting events.

No one, to my knowledge, has suggested that the sporting event was other than a fair and square test, and I agree that the result, given ordinary conditions, was inevitable, in spite of Mr. Jones's great knowledge and ability, but we must not forget to give just a little credit where it is due.

I still stick to my challenge, and extend it further—*i.e.*, conditions exactly as before, but for a distance from 50 to 500 miles, solo or sidecar. I am a private owner with no trade interest at present, and, although in khaki, I am in such a position as to be kept well in touch with right up-to-date practice in the motor cycle world, and if "Be Sportsmen" will not ignore me altogether I feel sure we could have a real good sporting event worthy of the "great pastime and industry."

BERT HOULDING (M.T., A.S.C.)

Sir,—In the issue of January 3rd I saw letters from "Stiffy's Master" and S. A. Marks, gentlemen who know many things, but keep the information to themselves.

Their complaint of the W.D. Triumph is its low max. speed. I think it is only fair to this machine to mention a few particulars of why it is slow, and should not be compared with Brooklands specials, T.T. racers, etc., and then give my own experience of the same model, but in the hands of a private owner.

The W.D. Triumph is fitted with a top gear ratio of 5 to 1, as it is intended as a heavy-duty machine, suitable for cross-country work, etc. Also the carburetter is fitted with a jet No. 28. This I measured and found it to be .03in., or as usually called a 30 jet. This is generally considered small for an engine of 550 c.c. capacity.

I cannot remember what max. speed I got with the 5 to 1 gear, as it was delivered in April, 1915, but know a similar model which can touch forty miles per hour with this gear ratio when pulling a sidecar.

I have tried top gear ratios of 5, 4½, 4¼, and 4 to 1; the latter, with a .035in. bore jet, makes it quite a fast machine. I use a 4¼ gear, as the large sprocket caused the chain to rattle in the chainguard when the chain got slack. I am not fond of very high speeds, but my experience is as follows:

Using 4¼ to 1 gear, standard jet, standard roadster timing of valves and ignition, and Scotch petrol, I got fifty-three miles per hour. Again, as above, but with the .035in. bore jet and white spirit, I got fifty-five miles per hour. I exceeded these speeds with a Senspray carburetter, but D.O.R.A. prevented me from getting definite figures. The speeds mentioned are taken from a Bonniksen speedometer, which is considered as true as any.

I add the usual disclaimer. TRIUMPH.

Partick.

A MIRACULOUS PLUG.

Sir,—May I confirm all that "Ixion" relates in his "Occasional Comments" with reference to the Sphinx Mark C25 plugs, which I can characterise as only a little short of wonderful.

The machine in question was a Scott combination, and, not being able to obtain the plugs recommended by the makers, it was with dismay that I saw the machine rapidly ruin plug after plug of various well-known makes, which *would* work while other types which were tried refused to work at all. In no case would the machine start until the plugs had been taken out and cleaned and primed with petrol, even after a short stop, and top speed with sidecar empty was about 26 m.p.h.

Eventually the Sphinx people, whose plugs I had not used before in this engine, advised me to try their Mark C25, when I was agreeably surprised to find the speed increase to 45 m.p.h. on a private road with throttle half open, while on low gear the engine fired quite regularly at 3 m.p.h.

The machine now starts quite easily, and the plugs have never been out since they were put in some weeks ago.

It is true that about the beginning of the experiment I made a winter adjustment to the Binks carburetter, but that should not greatly affect matters. Usual disclaimer.

BATEMAN SCOTT.

HOW MANY GEARS?

Sir,—I was greatly amused and vexed to find two able contributors like "Ixion" and "Chinook" wrangling over the question of three and four-speed gears. In my recent motor cycling experience—at one time I rode an old accumulator Wolf and in those days twenty gears would not have helped us much—I never owned a machine on which I saw any dire necessity for more than two gears.

I live in Scotland, which I have toured extensively, so your touring readers will know what that means. But let me note this: I have never attempted to run a sidecar on a 3½ h.p. engine. To my mind, that is the essence of folly, and ultimately ends in trouble and expense. I have seen it done too often by novices not to know.

My last mount, which I parted with on crossing in 1914, was a big single of close on 600 c.c., with two-speed gear.

In July, 1914, I circled Scotland in six days, with a 10 stone passenger, *viâ* Aberdeen, Inverness, south side of Loch Ness to Fort William, Oban, Callander, and Edinburgh, and, with the exception of the road south side of Loch Ness, had little low gear work. Again, a week later, I went from Stirling to Ballachulish Pier in exactly four hours, with empty sidecar, *viâ* Callander, Tyndrum, Glenorchy, over the Black Mount, and through Glencoe, almost an average of 25 m.p.h., *and never once used the low gear.*

I believe that a large number of the older school—not the Triumph and Douglas D.R.'s of the war period—will agree with me that, given the engine power, two gears are quite sufficient for them. LIEUT. (Retired).

Edinburgh.

3D.

THE PRICE of THE MOTOR CYCLE TO BE RAISED TO 3D. ON FEB. 7th.

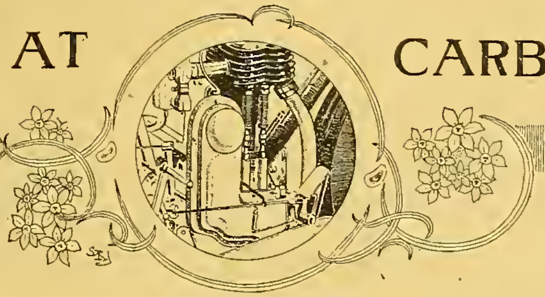
This further increase is necessary owing to the drastic restriction imposed on the import of paper and paper making materials during 1918 and the consequent heavy advance in the cost of paper, but the price will be reduced as soon as circumstances permit.

The subscription rates will be correspondingly raised on renewal or to new subscribers:

British Isles	**15/2**	**per annum, post free.**
All countries abroad..	**19/6**	**,, ,,**

All subscriptions current at the time of reducing the price will be proportionately lengthened for the benefit of each subscriber.

FUEL LOSS AT CARBURETTER.



Points of Wastage in Carburetter Design.

PETROIL lubrication in two-strokes has no doubt had its day, but I think there is one thing which it has taught us.

We have all been struck with the enormous amount of oil collecting around the carburetter. We find it covering the float chamber, the outside of the jet, the extra air inlet, and the main air inlet; in fact, all over the carburetter inside and outside. We clean the carburetter bright before we start out on a run, and in five or six miles it is as oily as ever. This oil, then, is evidence of a continual loss of petrol. And we must remember that for all oil visible or wasted we must multiply our loss of petrol by sixteen.

In an engine with separate lubrication we have the same losses going on, but not made apparent as in the case of petroil. In an article on "Carburetters" in *The Motor Cycle* of November 1st, "Chinook" drew attention to the waste of petrol in a jet carburetter. It is intended here to analyse these losses a little more closely.

We will first consider the losses due solely to leakages at joints, unions, etc. The float chamber screw top is a great culprit in this respect, while the unions on the petrol pipe do not lag far behind. In works where a considerable amount of petrol piping is used it is necessary that all joints in screwed piping be absolutely tight, and the best practical method of securing this is found to be by smearing the thread with a stiff solution of shellac dissolved in methylated spirit. The thread is then screwed home and the shellac provides a film which is impervious to petrol *so long as the screwed thread is undisturbed*. The moral is—make your screwed joints with shellac and do not unscrew them unless absolutely necessary. When they have to be disturbed remake with shellac.

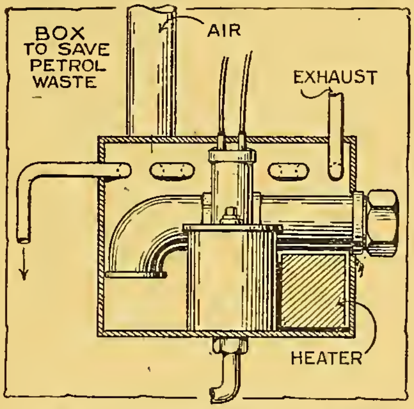


Fig. 1.—An effective method of stopping petrol wastage would be to box the carburetter.

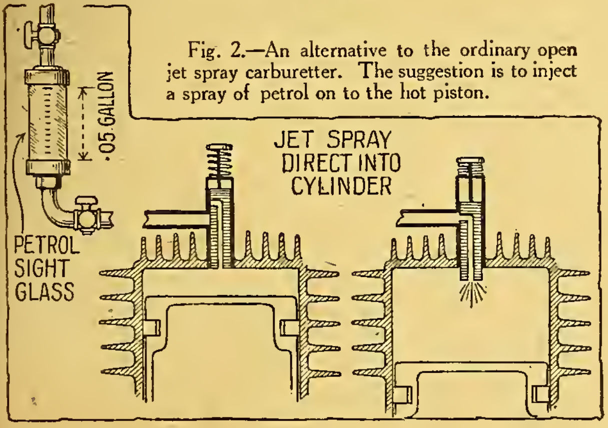

Fig. 2.—An alternative to the ordinary open jet spray carburetter. The suggestion is to inject a spray of petrol on to the hot piston.

For float or flanged joints it is usual to use asbestos millboard soaked in water. This makes a good joint when the flanges are screwed up.

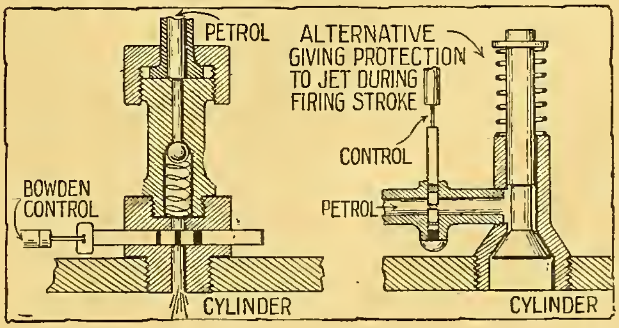
So much for pure leakage. We now come to the losses due to the exigencies of carburation.

Blow Back.

If we take the trouble to observe the jet of a carburetter when the float is depressed to flood it, we notice that a spray of petrol ½in. to ¾in. in height comes out of the jet. Now every suction stroke there is a jet of petrol two or three times as great as this sprayed into the centre of the carburetter. Some of it is vaporised and some of it carried forward mechanically by the air to the cylinder. It is worth while at this point to consider what amount of air is passing to the cylinder and under what conditions. Let up suppose the cylinder = 500 c.c. = 30.5 cubic inches. Engine running at 1,200 r.p.m. There will in this case be 600 suction strokes per minute.

We cannot expect the full capacity of the cylinder to be filled; we will, therefore, suppose 20 cubic inches of air drawn in during suction stroke. This through a 1in. inside diameter pipe gives $\frac{20 \times 600}{.7854 \times 60} = 254.6$ inches per second speed of air (average speed) through induction pipe. We have assumed that the cylinder was only two-thirds full when inlet valve closed; we may therefore take it that the air was travelling at at least its average speed when the valve closed. By thinking of this speed 254.6 inches (21.2ft.) per sec. we are enabled to imagine what will happen when this column of air is brought to a sudden stop. There will be

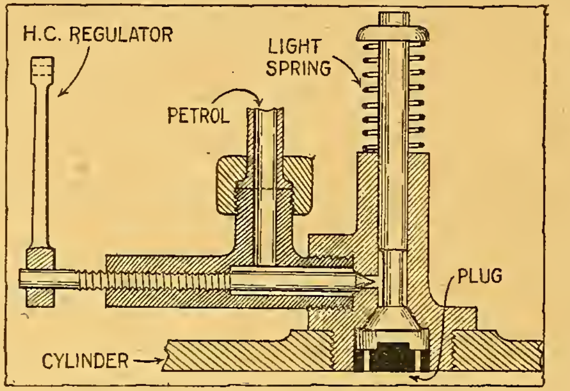
Fig. 3.—Showing operation of suction stroke, and an alternative design.



Fuel Loss at Carburetter.—
an expansion of the air back through the carburetter and its air orifices. This "blow-back," as it is called, simply flings petrol into every corner or crevice of the carburetter.

Notwithstanding the clearness with which we can see all this we have up to the present been quite content deliberately to waste 25% or 30% of our petrol if we could at the same time run our engine without bother. Now that petrol is, with us, like the memory of a dear departed friend, we are beginning, as is the custom with human beings, to be troubled with "past regrets." We must make up our minds in future, however, not to keep the petrol dealer going on the same lines as the mustard manufacturer, who lives by what we waste rather than by what we use.

The only method really certain of getting the best out of a jet carburetter from the point of view of petrol economy would seem to be to box in the whole contraption, leaving only an orifice for air with a rather long suction pipe (see fig. 1). Incidentally the box would be a smooth fitting, easily cleaned, which would keep out all road dust. The box would be airtight, and a bypass could be taken through from the exhaust, which would greatly assist in the vaporisation of the fuel.



AN ALTERNATIVE TO ORDINARY CARBURETTERS.

Operation: M.O.I.V. (inlet valve) arranged to open one-third to half-way down stroke. Partial vacuum opens petrol valve and a charge is drawn into cylinder through the jet regulator. The petrol is vaporised by heat of piston and cylinder assisted by partial vacuum. The plug shown acts as stop for valve, as a distributer, and also imparts heat to the charge on its way into the cylinder. The arrangement could be screwed into exhaust cap. M.O. inlet valve admits required air. This being independent of carburation can be exactly regulated.

An alternative to the ordinary open jet spray carburetter is here suggested.

The arrangement is to inject a spray of petrol on to the hot piston head and then to bring in the air to make a suitable mixture.

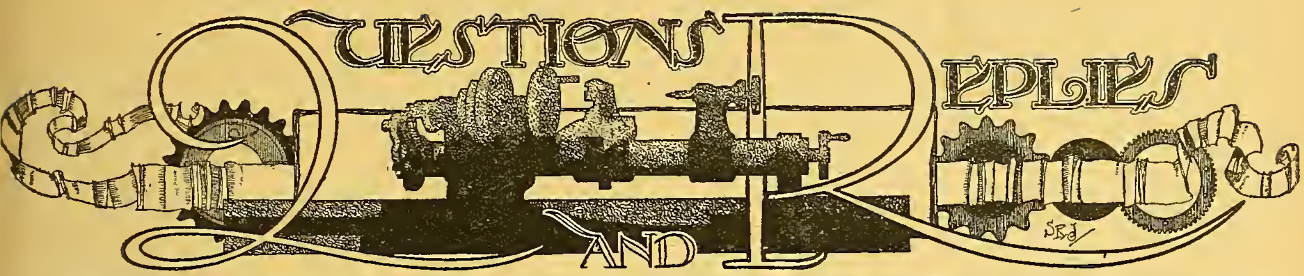
In order to do this the inlet valve is made to remain closed for the first half of the suction stroke, thus inducing a partial vacuum in the cylinder. This lowered pressure operates the jet, as will be seen by methods made clear in the sketches (figs. 2 and 3). The inlet valve opening at half stroke allows air to enter and form the mixture. No carburetter is needed and nothing passes through the inlet valve except air. The petrol is vaporised by dropping on to the hot piston head, vaporisation being assisted by partial vacuum. Starting up from cold will be easier than by ordinary carburation, for we know it is a common practice to inject a few drops of petrol into the cylinder to enable one to get an easy start in cold weather.

The sketch also shows an arrangement for feeding the petrol.

The methods here shown are capable of being varied in a number of ways to carry out the same object. A petrol engine carburetted on the lines suggested should give a better m.p.g. figure than the ordinary engine.

ENGRO.

HISTORIC WINDSOR. Windsor is one of the most ancient and picturesque of towns, and was a frequent resort for London motor cyclists in peace times. The sidecar in the foreground is a Rudge.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not must be accompanied by a stamped addressed envelope for reply. Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Oxidising Steel.

? Will you please tell me the process for oxidising steel (blue) similar to that of guns and other firearms?—F.A.P.W.

The bluing of steel is a trade in itself, and its successful accomplishment necessitates the use of several trade secrets. You might care to try the following method at your own risk: Prepare in a glass jar a mixture of 200 grammes of bichloride of iron and 200 grammes of iron filings—the latter very fine, perfectly washed, and entirely free from grease—and 100 grammes of sulphuric acid, and stir together. The precipitate that will be formed during this process may be used for oxidisation, being applied by means of a sponge or pencil brush (made of spun glass wire) to the part to be oxidised, which has been previously thoroughly cleaned. The part to be oxidised is then heated in a steam or vapour bath, and afterwards dried in hot air. After drying it is left in boiling oil for fifteen to twenty minutes, and afterwards thoroughly cleaned.

A Deal in Stolen Machines.

? I advertised my Triumph combination in a recent issue of *The Motor Cycle* in the exchange column. In reply to the advertisement two men came from Harrogate two days later bringing a Bradbury outfit. We agreed to exchange, I to pay £8. I paid part of the money and lent them a new motor coat and an overcoat, which they promised to return on the Monday, but failed to do so. They promised to come again in a fortnight or so for the remaining money. They did not arrive for six weeks, and then came without the coats, so I did not pay them. On the following Thursday the police came and demanded the Bradbury as a stolen machine, saying the two men were locked up at Leeds as the thieves. The police also stated that my machine was sold at Taunton, and they did not think I should be able to claim it back as they thought it was sold for cash. Will you let me know what to do?—F.W.T.

We are afraid you are in rather a difficult osition with regard to the two machines —both the one that you purchased and your own that you lost. As the machine hat you took was a stolen machine the revious owner may claim its return, and, we are afraid, you will have no hold upon . On the other hand, of course, the urchaser of your old machine may be ompelled to return it, and it is up to you to find out who the present owner is, by means of the proceedings that presumably are about to take place at Leeds Assizes, and then to request the present owner to return the machine to you. He, in return, should be able to recover any cash he paid for the machine from the man to whom he paid it, but whether he obtains this cash or not will not, we believe, prejudice in any way your claim to have your machine returned.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

Overheating.

? I have a motor cycle and sidecar fitted with a 3½ h.p. J.A.P. engine and Armstrong three-speed gear. It has run well since it was taken down and decarbonised three months ago until a week or so back, and will now only pull with any strength at all on lowest gear, which, in a few minutes, makes the top of the exhaust pipe red hot. The spark is good, and the carburetter appears quite in order. The engine will race on low gear when once started, but slows up and stops immediately on changing to second gear unless, of course, down hill. Instead of the usual sharp crack from the exhaust I notice more of a "thud" than otherwise — quite a different sound from what it should be. The gears have just been overhauled and renewed.—F.A.J.H.

First of all make sure everything is free. This can be done by taking out the plug and turning the engine over by means of the back wheel with the top gear engaged. You may find that an accumulation of mud inside the guards is preventing the wheels from turning freely. Next replace the plug and test compression. Make sure there is no leaking round the valve caps, etc. Take out the valves, and, if necessary, grind them in. Try a new plug, correct adjustment of valve tappets, and finally check the valve timing, which may possibly have slipped and be the sole cause of your trouble.

M.E.P.

? *The Motor Cycle*, dealing with the new 1918 Harley-Davidson machine, uses some terms and expressions which I—a novice—do not quite understand, and I should be grateful for an explanation of them. They occur in the latter portion of the paragraph entitled "Ignition and Timing." What are the m.e.p. curves, and what is the meaning of the compression ratio 4.12 to 1?—H.E.C.

M.E.P. means "mean effective pressure"—that is to say, the average pressure of the explosion on the piston throughout the length of the stroke. The "compression ratio" means the ratio between the total cylinder volume with the piston at the bottom of the stroke and the compression space with the piston at the top of the stroke. These subjects, and others of a similar nature, will be dealt with shortly in articles in *The Motor Cycle.*

Engine will not Start.

? I have had my engine down and the timing wheels out. I also had the magneto repaired, and it gives a good spark. I am sure I have got the valve timing correct. Now when I prime the engine it will go all right for about fifty yards and then stop, and if I prime again it will do the same. I might say it is getting petrol all right. Would a motor cycle run fifty yards firing all the time if the magneto timing and valve timing were wrong? I myself do not think it would, so if you could let me know the cause I should be grateful. —C.F.

The trouble is almost undoubtedly due to the fact that in assembling the machine —probably in attaching the carburetter—you have omitted to see that the carburetter or induction pipe unions are quite airtight. If this be the case, the reason why the machine will not run is owing to too weak a mixture. Evidently the timing is correct. On starting up the engine runs on the fuel you have injected, and immediately this runs out and it is solely dependent on the carburetter it stops. To assure yourself that carburation is to blame, pour scalding water over the induction pipe, thus thoroughly warming it, and probably your engine will start and run irregularly without an injection. Then, with the engine just running, bind suspicious joints with insulation tape. The engine will alter its speed when you strike the leak.

Transferring a Number.

? I have bought a motor cycle and sidecar, which I intend to store until we are allowed to ride again for pleasure. Will you kindly give me the necessary information as regards licences and registration? Shall I have to notify the change of ownership? If so, will you please instruct me? Shall I have to take out licences and registration before I am able to ride?—B.H.

All you need do is to have the registration transferred to your name, if the previous owner has not already cancelled it. Nothing else is required. You apply to the clerk of the county or borough council where the machine was registered and give full particulars as to change of ownership. You need not take out any licences until you use the machine.

Removal of Tappet Guides.

? What is the best method of removing tappet guides from a 1910 3½ h.p. Triumph? I have obtained new guides and tappets, but find difficulty in removing the old guides. I am afraid of injuring the crank case, but am enough of a mechanic to do the job more carefully than will be done by a garage. Is there any special tool necessary? I have plenty of tools for ordinary fitting, etc., and I have a holy horror of the ordinary mechanic.—J.C.

The removal of the tappet guides should be begun by means of a right-angled punch. Before you can attempt the job you must remove, of course, the cylinder and the timing gear case, and then you may drive the tappet guides upwards from inside the timing gear case. When the guides have been started by means of the right-angled punch, the movement may be completed by means of an ordinary straight punch.

Use of Petrol.

? My occupation is that of a country water rate collector and inspector. The district is an area within a radius of ten miles of a city. It is not traversed by motor 'buses, and is purely of a country nature, my clients being mostly farmers. I have only taken this position during the war, having taken the place of the regular collector, who was of military age. I have been invalided from the Royal Navy. My age is fifty-four, and doubtful health will not permit of my riding an ordinary cycle. The above is the *sole* purpose for which I wish to use the machine, but I am wondering if I can safely use what little petrol I have without a petrol licence, which I am now unable to obtain.—W.J.M.

The opinions of individual benches of magistrates vary to such an extent that it is impossible to advise anyone as to whether he may use a machine with impunity if there is the slightest room for doubt in the matter. We should imagine you would be quite safe, but regret that we cannot give you any definite ruling. You would be well advised to mention the matter to your local police officer.

Making a Kick-starter.

? I am making a kick-starter for my motor cycle, which is fitted with an Armstrong Mark VI. hub gear. Will you kindly inform me on the following: (1.) What should the gear ratio be between the chain sprocket and the kick-starter? (2.) What length should the kick-starter crank be?—J.S.N.

(1.) The gear ratio between the chain sprocket on the hub and the sprocket on the kick-starter could conveniently be anything from about 1.75 to 3. Perhaps the most satisfactory would be about 2.3. (2.) The length of the crank is dependent on the gear ratio, say between 6in. and 7in. with the 2.3 ratio.

Liquid Hydrogen as a Petrol Substitute.

? Is liquid hydrogen a possible fuel for motor cycles? Are any experiments being made upon it? Apart from the great problem of storing, surely the idea is feasible.—O.W.

The application of liquid hydrogen as a fuel is quite impossible. The first objection is the cost, which is insuperable; the second is the difficulty of storage; and the third is in the nature of the explosion, which is far too violent for use in an engine. Hydrogen is the most difficult of all ordinary gases to liquefy, and, while its liquefaction is a common accomplishment in the laboratory, we have never heard of any experiments being made upon the use of liquid hydrogen as a motor fuel.

Changing the Gear Box.

? I should be obliged if you would give me particulars regarding Douglas gear boxes. Can a three-speed Douglas gear box be fitted to a Douglas machine that is at present fitted with a two-speed Douglas gear box? What is the correct size of Amac jet for a 2¾ h.p. Douglas during the winter months? I am at present troubled by heating up on the slightest incline, till finally the machine stops completely. Please let me know the cause and any possible remedies.—F.O'N.

A three-speed gear box could be fitted to a two-speed Douglas if you consider it worth the expense. If a 1913 Amac a 28 jet, if 1914 26 or 27, if the latest model 26. Probably your trouble is due to a weak exhaust valve spring, or to too much clearance between the exhaust valve tappets and the bottom of the exhaust valves.

Starting from Rest.

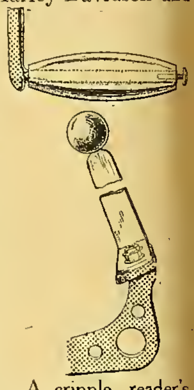
? (1.) I have always been under the impression, and have always pursued the course, that when first taking out a machine on to the road it is quite correct to start off with the low gear engaged. My friend has heard from a garage proprietor that this is not the case, but the machine should be started in high gear. The machine referred to is a 1914 7-9 h.p. Indian. (2.) Does your answer to question (1) also apply to a motor car?—C.R.S.

(1.) It very much depends upon the circumstances. If you are pushing off to start on a level road you engage the high gear. Naturally, if you start by means of a kick starter and use the clutch, the low gear should be engaged. In cases where the compression of the engine can easily be overcome when pushing off, the engine is more likely to fire at once on the low gear on account of the higher revolutions, but with a sticky engine, or one which has a high compression, it is obviously easier to overcome the resistance when the top is in engagement. (2.) In the case of a motor car it is invariably the practice to start on first, or lowest, speed, unless the car is on a down grade or the low gear is so low that the second is enough for the purpose.

READER'S REPLY.

Machines for Cripples.

I am unable to use my feet except for standing and walking short distances, and that with the aid of irons worn on the legs and crutches. I have been riding over six years, and have found my present machine—a 7-9 h.p. Harley-Davidson and sidecar—to be the most satisfactory. Only two alterations, both quite simple, were necessary. First, a lever bolted on to the brake pedal so that it could be operated by hand. Secondly, the right-side pedal of the kick starter (1915 machine) was removed from its spindle, a plain boxwood handle turned to be an easy fit and of such a length as allows the spindle to project $\frac{1}{16}$in. beyond it. The end of the spindle was then drilled and tapped and a mushroom-headed bolt fitted to keep the handle in its place. I think the accompanying rough sketch will explain my meaning. I hope this will prove of use to your correspondent. To my mind, driving from the sidecar is attended by the following disadvantages: The back wheel does not grip the road very well and is prone to skid when braking and ascending hills, and one cannot carry a passenger except on the carrier.—E. J. L. STRONG.



A cripple reader's alterations to a Harley-Davidson kick-starter.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller, but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

More about Fuel.

WE have said before, and we offer no apology for saying again to our readers, that anything and everything likely to throw any light on the fuel question is a matter of primary importance to all motorists, and one that should before all things receive their gravest consideration. Consequently we would direct the attention of all motor cyclists to two extracts that appear in this issue, both bearing on the fuel question—though they are in very different tones.

The first of these extracts is from the motorists' arch-enemy, the *Daily Mail*, while the other is from a very different journal, the *Board of Trade Journal*, the first appearance of which in its new form we announced some few weeks ago in our columns. The *Daily Mail* extract consists of some remarks by Mr. Shrapnell-Smith—an important officer of the branch of the Board of Trade that deals with all petrol and allied matters—and the tenor of these remarks is to the effect that economy is even more important now than it has been for some time past, and it is also suggested that no alleviation of the situation is to be expected for some considerable time. Mr. Shrapnell-Smith is anything but an anti-motoring fanatic, and is also not the man to make wild and alarming statements without full and mature consideration. It is therefore probable that those motorists who are expecting an early relief from their present straitened position are doomed to further disappointment, and that the more energetic agitators among them are breaking their heads against a wall.

The far more important of our two extracts—that from the *Board of Trade Journal*—is also far more interesting, though unfortunately but little more hopeful, as far as the private motorist is concerned. The Ministry of Munitions, from whom the extract emanates, states that full development of home sources of fuel has been restricted by the perfectly legitimate though unfortunately conflicting claims of the various War Departments primarily in the sphere of labour. Consequently progress has naturally been much restricted.

Nevertheless, it is gratifying to learn that a Ministerial Department is fully alive to the possibilities of the case, and that as much as possible has been and is being done to forward these desirable ends. All that the motorist can do is to watch developments and take care that interest in the matter is never allowed to flag.

The Price of "The Motor Cycle."

OUR readers will have noticed that we have been compelled to raise the price of our journal, commencing with the first issue of next month. *The Motor Cycle* was first issued in 1903 at 2d., but it was soon reduced to 1d., which remained the price until last March, when war conditions made it necessary to revert to the old price. Now, as explained in the publishers' recent announcement, a further increase to 3d. has become necessary.

Owing to the drastic restrictions placed on the import of paper and paper making materials there is a serious shortage, and this, combined with the very great increase in the price of paper and the cost of production generally, has rendered this step imperative, the only alternative being a reduction in the size or quality of the journal. We feel sure that the majority of our readers would prefer to pay the increased price; in fact, we have received a number of letters to the effect that the writers would continue to take *The Motor Cycle* weekly even if the price were increased to 6d. To these we extend our best thanks. Our readers can assist the publishers in effecting an economy in paper by placing definite orders for the regular supply of *The Motor Cycle* either from our publishers or a newsagent, and by handing their copies, after perusal, to the Post Office authorities to forward to the troops, as is done in the case of the monthly magazines.

An index to the advertisements in this issue will be found on the page facing the back cover

OCCASIONAL COMMENTS

BY 'IXION'

The Perfect Terminal.

ONE of the criticisms passed on my suggestion that the magneto may eventually disappear from machines which carry accumulators for lighting work has been that it will involve a return to the bad old days when electrical cables snapped off at their connections with sickening regularity at the rate of one a mile. Has anybody noticed why our cables never snap off nowadays? Simply because the modern type of connection, whether to a single-cylinder magneto or a twelve-cylinder lighting, starting, and ignition set, supports the insulation as well as the internal wire. In the old days the thin woven flexible wire carried the entire weight of the cable, which was seldom supported in clips. To-day every terminal in the electrical system of any decent machine is so designed that a stiff piece of metal takes the weight and the thin internal wire has nothing to do beyond effecting electrical contact.

Another Crank.

I AM not the only lunatic on our staff, you know. One of our sister papers boasts a writer who is nearly as dotty as I am. He has been an awful bore for the last week on the subject of radial engines, for which he has conceived an absurd enthusiasm with a view to light cars, which are as much his King Charles' head as flat twins are mine. He has apparently smuggled himself into some aero shop, and seen a radial engine which weighs about 2 oz. per h.p., and then he went home and dreamed of a 2 cwt. light car, with a deck which was wholly available for passengers and luggage, the engine being gummed on the front panel, and being little thicker than a postage stamp.

Why Aluminium?

FROM these Utopian dreams and philosophisings, let us descend to hard facts with a pancake landing which will concertina our undercarriage. Will some technical expert tell us why motor cycle gear boxes are usually made of aluminium? The official answer is because aluminium is light. The true answer is because Adam was descended from a sheep. Just think. The casing portion of the average motor cycle gear box consists of about two cubic millimetres of metal: whether you make it of *papier mâché* or lead affects the gross weight of the machine just about as intimately as whether you shave before or after your ride. No. Motor cycle gear boxes have aluminium casings because car gears are usually enclosed in aluminium: and, where cars are concerned, the gross amount of metal may justify the selection of the metal. This is the sole reason why motor cycle gear boxes are of aluminium. Incidentally, it is a rotten bad metal for the purpose. Thrice during a recent twelvemonth the businesslike hum of a certain gear box which then disgraced my garage was augmented by a more soprano-like and strident hum, indicating that the ball bearing housings had worked loose in the light plates of aluminium, wherein their optimistic designer had hoped they would find an eternal resting place. I have owned one gear box which has never given me any trouble: and its casing is of phosphor bronze. Phosphor bronze, let me add, is cheaper than aluminium: quite as easy to work: infinitesimally heavier in such small quantities: and a million times more satisfactory.

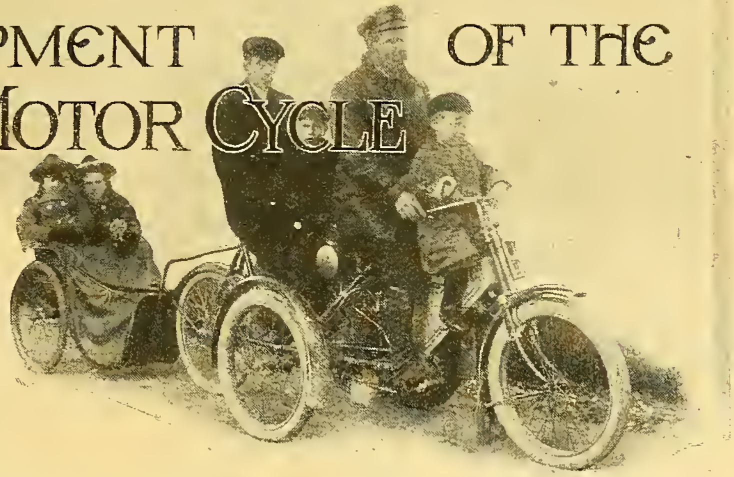
Some Questions for Mr. Aston.

MR. ASTON'S article on altitude stimulated a great deal of discussion, and I will ask him to tackle a topic into which he betrayed a number of us who possess more enthusiasm than information. The company started with "ceiling," and finally wandered into speculations about flying through space to visit the moon and the more adjacent planets. Opinions on the subject were divided, especially when points relating to gravity were superadded to the aerodynamics of space. Finally, the Ulstermen asserted that flying through space was as much a mechanical impossibility as perpetual motion, whilst the Nationalists stood irreconcilably by a theory that, given a compressed air supply for the carburetter, an oxygen apparatus for the foolhardy pilot, and some form of buoyancy for the supporting surfaces, the Cuthberts of the next great war would probably hie away to the moon with sufficient tabloid provisions for a prolonged sojourn. I purposely issue my invitation to Mr. Aston through this column, in order that readers may have a week or two in which to puzzle their brains on the topic before he pontificates upon it.

The Edison Accumulator.

A CORRESPONDENT suggests that an electric lighting set for solo machines could easily be furnished as soon as peace returns if makers would adopt the Edison accumulator. I have never owned an Edison, but he implies that you can drop it off the top of the Eiffel Tower, or squash it under a steam hammer, or short it by leaving a tyre lever across its terminals all night, and it comes up smiling for the next round. I heard some of these Edison yarns a year or two back, and wrote to the concessionnaires for particulars, picturing myself writing an article for *The Motor Cycle*, which the Editor would print in ruby capitals as a boon and a blessing to our community. The Edison reply put the lid on my rosy dreams, for they wanted £11, I think it was, for the very modest size of accumulator which I then required. However, it by no means follows that we may not soon get a good solo set. One or two dynamos of compact dimensions are already thoroughly reliable, *e.g.*, any touring motor cycle could readily accommodate the type of Lucas dynamo which figures on the Morris-Cowley car, and I know that Messrs. Lucas have been working hard to evolve a sound accumulator for the purpose.

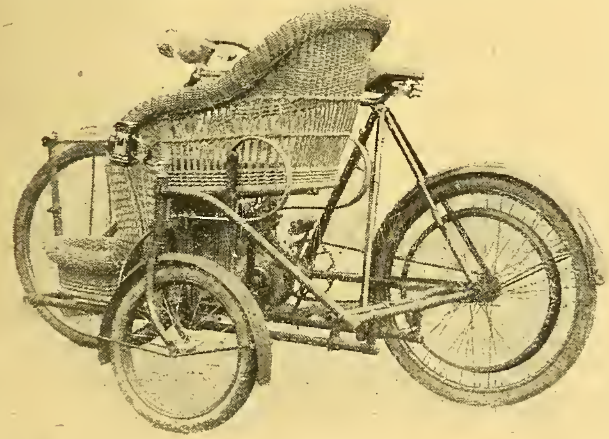
THE DEVELOPMENT OF THE PASSENGER MOTOR CYCLE



THE DEVELOPMENT OF THE SIDECAR.

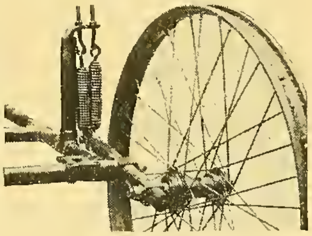
OUR previous review practically covered what may be called the period of the genesis of the passenger motor cycle, and although at the time it was not fully recognised, there is no doubt that by the end of 1905 the final triumph of the sidecar was assured. From 1906 to the present time very few radical changes had been introduced into the practice of sidecar construction, and indeed we may say that with one single exception nothing of even a mildly revolutionary nature has been introduced since the introduction of the flexible sidecar in 1903.

This exception was the castor wheel sidecar, which made its appearance on the market in 1905. As the name suggests, the castor wheel was a wheel that trailed in a fork from a head similar to the steering head of a cycle, and this construction is made perfectly clear from the accompanying illustration of a castor wheel sidecar made by Messrs. Mills and Fulford in 1905. Of course, in later years, the actual method of fixing the trailing wheel was considerably altered, but the principle remained the same. There is no doubt that for cornering the castor wheel was an enormous advantage, but like the flexible sidecar the castor wheel exercised little check on the skidding of the cycle; also while the castor wheel sidecar remained vertical with the machine at rest, it was rather difficult to handle, because as soon as the machine was pushed backwards the wheel would swing round and consequently would not form a fixed pivot. Those readers who have noticed our remarks on reversing with the gasbag attached will readily perceive what is meant.



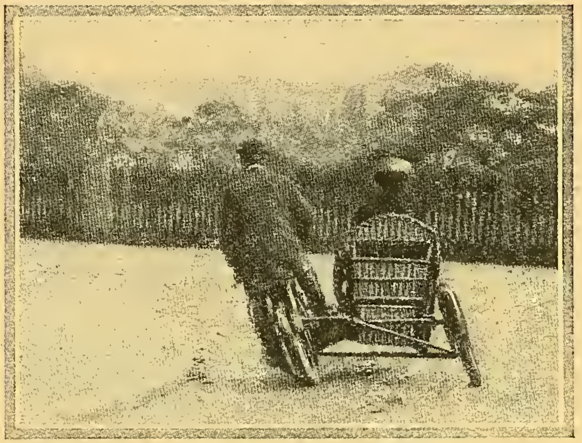
The castor wheel sidecar. This type was very pleasant to drive, but was, like the flexible, liable to skid, and it also had the drawback that it was awkward to handle in the garage.

The introduction of sprung sidecar wheels took place about 1908 and promised to bear great fruits, but like many other ideas that started very well they are now considered a somewhat questionable recommendation. Breaking away a little from our chronological order, we may refer readers to an illustration reproduced in *The Motor Cycle* of September 30th, 1908, showing an excellent system of sidecar wheel springing. This idea was purchased by Messrs. Chater Lea and used by them as late as 1913.



Springing the sidecar wheel. Attempts in this direction have never met with unqualified success, but this, one of the earliest efforts, gave complete satisfaction on the Chater-Lea sidecar. Without question the subject of sidecar chassis springing will be one to receive very full attention after the war

In 1906 had been illustrated a two-wheeled sidecar called the Auto Phaeton, and while this particular vehicle does not appear to have enjoyed any great measure of success, it was followed in 1908 by the Lowen sidecar, which was also a two-wheeled sidecar, and is shown attached to a Matchless motor cycle. In fact, the year 1908 was comparatively prolific in the production of passenger vehicles, and in December of this year was illustrated in *The Motor Cycle* a four-cylinder 20 h.p. tricar designed much on the lines of the modern Morgan, but of course very much larger. In this month also an excellent device known as Warr's passenger motor cycle was put on the market. This, as may be seen from the illustration, was a type of back car, but contained all told only three wheels, the rear wheel of the motor cycle being entirely removed, and a countershaft fitted in a position somewhere near that usually occupied by the rear hub, and the drive being taken thence to one of the rear wheels by a second chain. Like many other promising devices, Warr's passenger motor cycle did not have a very long life.



The combined rigid and flexible sidecar, a design full of merit, which was fated to a short life. This sidecar could be made either flexible or rigid at will, and the change could be made by the driver while travelling.

In 1909, as a kind of reminder that the flexible sidecar still had something to say for itself, although it had considerably declined in popularity, a most ingenious and excellent device was put on the market in the shape of the Appleby combined flexible and rigid sidecar. The illustration reproduced of a motor cycle and this sidecar chassis attached shows that the sidecar wheel leant over with the motor cycle, the distance between the wheels being invariable, but the main feature about it, which unfortunately is not shown in the illustration, is that the machine could be locked in an upright position by the simple movement of a small lever. Consequently, when the machine was stationary, movement of this lever would cause it to remain upright, and also when riding on treacherous roads the combination could be converted into the rigid type, and at a moment's notice rendered immune from skidding.

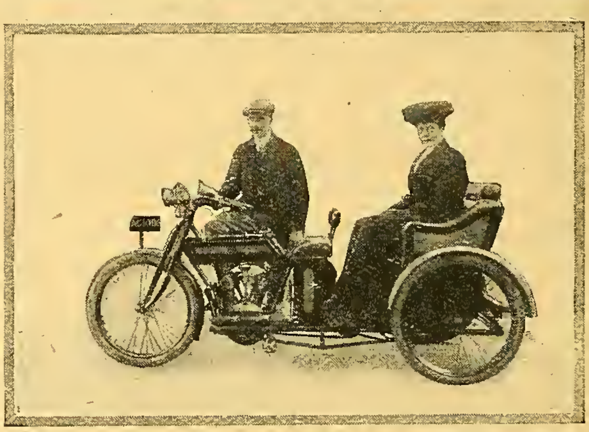
Sidecar on Right of Machine.

This illustration is also interesting as depicting the sidecar shown on the right-hand side of the motor cycle. It was, indeed, not until 1911 or 1912 that the fitting of the sidecar to the left-hand of the machine became practically universal, and throughout 1910 discussions were frequent in *The Motor Cycle* as to which was the better side for attaching the sidecar. In this year appeared a device that, like so many others to which we have already referred, did not meet with the success it seemed to deserve. This was a folding sidecar. Several of these arrangements have been put on the market, and the working of this particular example is made perfectly clear from the illustration. The advantages of a folding sidecar are, of course, too obvious to need elaboration—as, for instance, when circumstances necessitate taking the machine through a narrow gateway at frequent intervals.

The First Morgan.

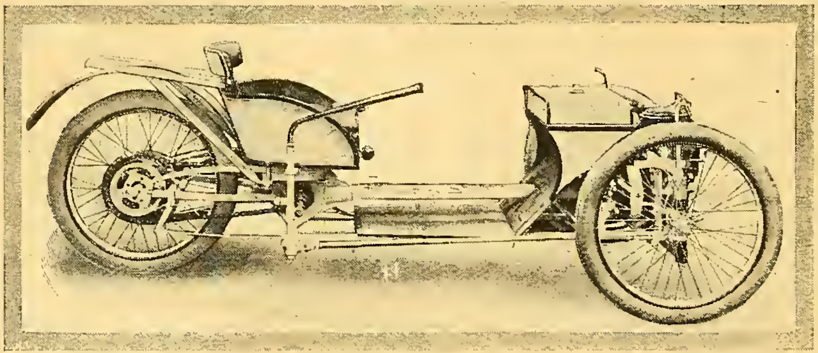
It will be noticed that the Pioneer Morgan was a very different vehicle from that now being manufactured, and it will also be seen that the power plant consisted of a single-cylinder engine.

If there is one feature about all these early passenger arrangements that more than anything else strikes a present day observer it is the exposed position of the passenger in practically every instance. The Lowen sidecar certainly was equipped with a hood, but the "dash"—if it may be called such—was so low as to be practically non-existent, and many observers in 1911 had come to the conclusion that if the sidecar were to develop any further two radical improvements were necessary. The first of these was the provision of better weather protection for the passenger, and the second was the provision of more permanent attachment between the motor cycle and sidecar; in fact, when the war broke out we had reached the stage when motor cycle and sidecar were turned out as a fixed combination without any intention in the maker's mind that they should be separated, except on very rare occasions.



A promising three-wheeled design that appeared on the roads in 1908. Many devices embodying less well-tried principles and of less pleasing appearance have been placed on the market since this machine made its début.

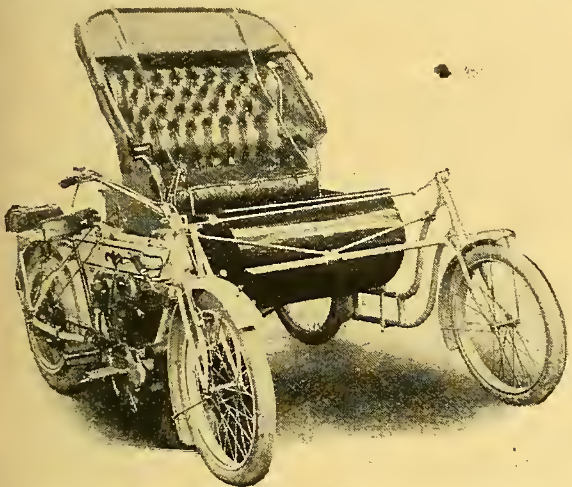
The first machine to illustrate either of these tendencies to any marked degree also illustrates them both, and may, indeed, be regarded from many



The first Morgan. There is no need to emphasise the difference between this, the first, and the latest products of the now famous Malvern firm.

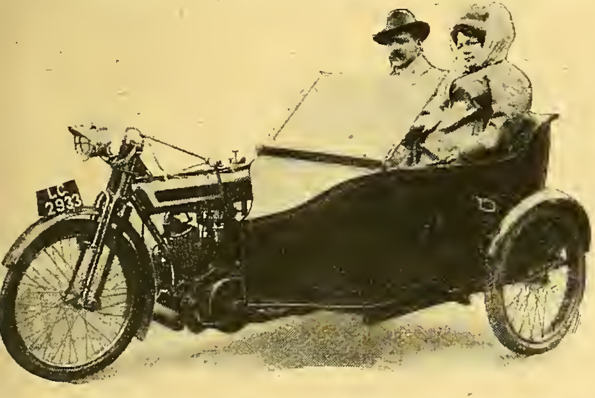
The Development of the Passenger Motor Cycle.—

points of view as well ahead of practice existing even now. This machine was first known as the T.A.C., later as the T.M.C. and Ogden, and our illustration of this combination, reproduced from *The Motor Cycle* of September, 1912, shows what an elegant and up-to-date appearance the whole provided



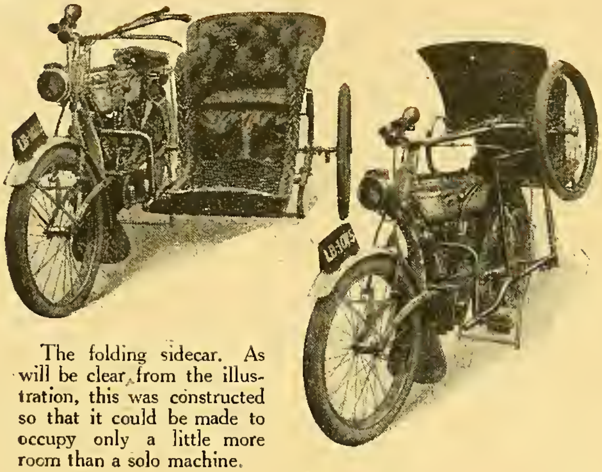
The Lowen two-wheeled sidecar. This type of sidecar made the combination into a four-wheeled vehicle and so liable to the car tax. It had several advantages, but this taxation question apparently outweighed them all in the mind of the public, for although complaints as to the merits of the system were extremely rare, its success was comparatively short lived.

It will be seen that the power plant consisted of a four-cylinder water-cooled engine with shaft transmission, and clutch and gear box arranged after car practice, while the sidecar as well as the motor cycle seat appear the very picture of comfort. Whether this machine will return after the war remains to be seen. As our articles for some time past have shown, there is an enormous class of riders who want a machine that can be used for solo work occasionally, although primarily intended for pulling a sidecar. The T.M.C. was not an ideal solo mount, for which purpose the steering renders it almost impossible, although we can see little improvement to suggest in its general design as a passenger motor cycle.



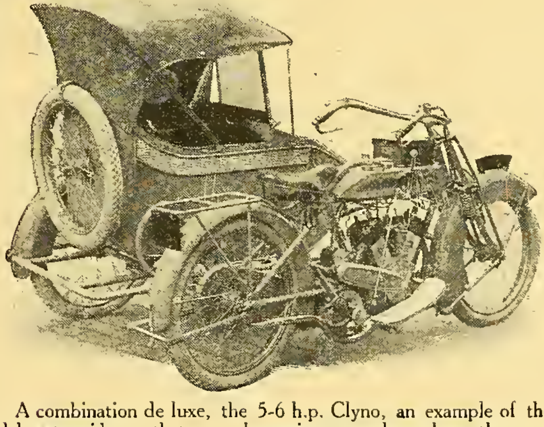
An example of the side by side sidecar which was driven from the sidecar seat It is quite possible that this will be a popular post-war type.

The general tendency towards elegance in those few years in which the sidecar enjoyed unrestricted development is shown in the last illustration—one of the 1916 model Clyno combination.



The folding sidecar. As will be clear from the illustration, this was constructed so that it could be made to occupy only a little more room than a solo machine.

The question of a sidecar to carry two passengers is one that has often come in for consideration. Personally, we think that the future of the two-seater sidecar is a very precarious one, but, of course, as has been proved time and time again, prophecy in such a matter is an extremely unsatisfactory undertaking. For this reason it is difficult and unwise to attempt to indicate with any pretence at authority along what lines the future development of the sidecar is likely to proceed, but most of our readers will be familiar with double-seated sidecars in which the driver and passenger sit side by side, the cycle itself having no passenger. Such machines have appeared on the market since 1913. The Scott Sociable is, perhaps, the highest development of this type, and, of course, except in casual appearance, really has nothing in common with the sidecar attached to the motor cycle. But the pioneer is, we believe, the machine illustrated herewith—the H.S.M. sidecar. In our opinion this type of machine will attain a fair measure of popularity after the war, and we may remind our readers that the Seal—a device of this nature made in Manchester—did attain a certain measure of success, while such a prominent firm as A. J. Stevens and Co., Ltd., had also turned their attention to a similar device.



A combination de luxe, the 5-6 h.p. Clyno, an example of the elaborate sidecar that was becoming popular when the war broke out.

ROYAL ENGINEERS

MILITARY NOTES.

THE M.T., A.S.C., AGAIN: A TRIBUTE.

AN APPEAL TO MOTORISTS.

WE have already referred to the excellent work of the Motor Transport Volunteers in transporting leave men across London at night time, and it gives us pleasure to publish another appeal for drivers. General Sir Horace Smith-Dorrien has stated that no form of voluntary war service is of greater value to the country, and the Earl of Chesterfield and Maj. C. R. Freemantle appeal to motorists to offer their services at 31, Walbrook, E.C.4. The hours of duty are from 11.30 p.m. to 6 a.m. one night per week, and petrol and tuition are provided.

* * *

THE M.T., A.S.C. AGAIN.

A RATHER belated letter on the subject recently discussed on this page, on the dangers of the M.T., A.S.C., comes from Cpl. R. N. Richardson, now in Salonica. He speaks from long experience, and we give his letter in full:

"Having read J. W. Parsons's idea of the work of the M.T., A.S.C., which appeared in *The Motor Cycle* on September 20th, 1917, I think his letter was very unfair. I cannot help but answer it. One would think he had never seen active service if he had not said so, and if he has he cannot have had much experience.

"I should like to ask him these few questions:

"Who drive the Tanks, the ambulances, move the heavy guns, take up the food and ammunition, and this while under shell fire half their time?

"Who were the last to leave their post at Mons, and when, where, and how did the A.S.C. receive the Loyal Wreath which they still wear on their cap badge to-day?

"Now we will take the D.R. who rides with the artillery and who is at times in more danger than the infantry. Mind you, a D.R. does not always complete his journey on his cycle—more often than not he has to complete it on a mule and on foot. And not only that, he is under shell fire and rifle fire very often.

"We have not only that to put up with, but we have also the troubles of the road, where there are roads, and where there are no roads we have to travel through ravines, rivers, mountains, and I can say in the winter we have something to go through. And a D.R. always carries out his duty, no matter how bad the weather may be.

"I have had two years' active service myself as a D.R., and I know what it is from experience in France, Belgium, Serbia, and other fronts in the Balkans."

* * *

HONOUR FOR SGT. HEALY.

SGT. J. HEALY, R.E., a Cork motor cyclist, who is at present serving as a despatch rider in Dublin, after a period of service abroad, was presented on Tuesday, January 8th, with the certificate of the Royal Humane Society as a recognition of his gallant act in saving from drowning the life of a woman who jumped into the Liffey. Healy saw service at the Dardanelles as a D.R., and was invalided home. For gallantry during the Dublin rebellion he was promoted to sergeant. He rode a B.S.A. in the 1914 T.T.

IN THE LAND OF SAND AND FLIES.
Members of the Army Signal Corps in Mesopotamia. All the mounts are Douglases.

A TRIBUTE.

FROM a communication we have received from Pte. J. W. Dickinson, M.T., A.S.C., we have taken the following extract: "I have been rather amused at some of the discussions regarding the Triumph. Having been a regular reader of your journal since its birth, and having had sixteen years' experience, riding everything from the 1¼ h.p. Motosacoche to the 7-9 h.p. road-eaters, I must say that with the exception of a stronger top tube, buffer spring, and cover for gear quadrant, the 'trusty Triumph' still can hold its own with anything for work in France. Granted its speed is not much above 45 m.p.h., but I am sure, if I had the same machine in private life and made a few slight alterations, another 10 m.p.h. could be added for work on our roads. Reliability is more important than speed in France. Simplicity, strength of transmission, and accessibility are the secret of the success of the trusty Triumph; it has also shone as a mud-slogger. There is no need for T.T. models near the line, and a good many other places; therefore, why crave for a speed mount? My only interest in the machine mentioned is that I always considered it the best single, and have possessed each model from the time when the manufacturers first made their own engine, in 1905, to 1914."

Lt. Victor Greaves, who lost his life during the great struggle for Cambrai. He was a keen motor cyclist, and a member of the Chesterfield Motor Cycle Club.

* * *

24 HOURS' CONTINUOUS RIDING.

WE received a message the other day from W. H. Elce, who is now despatch riding in Palestine. Elce is one of the many motor cyclists we helped to enlist in the R.E. Signal Service. In writing to his wife recently he stated that he had done twenty-four hours' riding without a break in the country round Jerusalem. He wished to be remembered to his former co-competitors in the T.T. We were very glad indeed to hear that he was still safe and sound. He also writes most enthusiastically regarding the behaviour of his countershaft Triumph.

* * *

AN AMERICAN COATALEN.

MR. FRED. S. DUESENBERG, the American designer and builder of many successful car, boat, and aeroplane engines, started his engineering career as a manufacturer of motor cycle engines. It was a Duesenberg engine which was fitted in the famous racing motor boat *Disturber IV.*, and similar engines, we understand, are fitted in many of the submarine chasers used by the Allies.

LONG SERVICE.

There is no necessity to quote exceptional cases of B.S.A. longevity, there are thousands of B.S.A. riders everywhere who, from personal experience, can testify to the remarkably long service which B.S.A. machines give. Year after year B.S.A. Motor Bicycles are giving invaluable service, frequently under the most arduous conditions, and with unfailing reliability. Freedom from worry and a saving of expense are two important advantages which have been largely responsible for the great popularity of B.S.A. machines.

OVERSEAS SECTION.

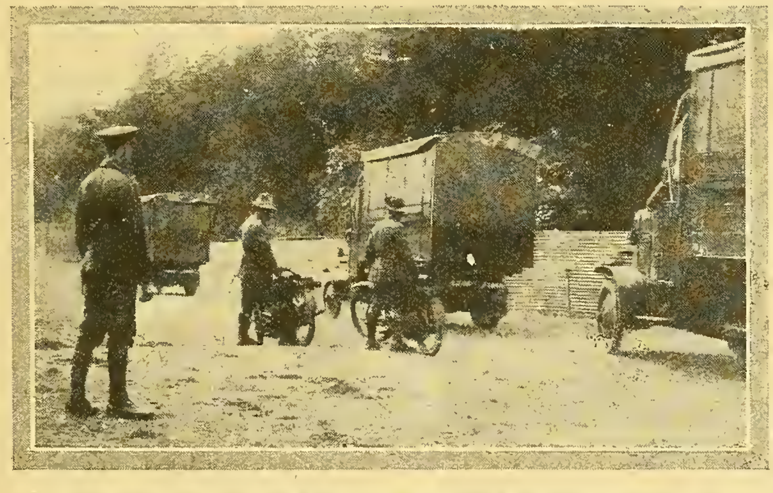
The Expressed Opinion of an Overseas Rider, which may or may not be Generally Approved.

Some Notes on Overseas Models. An Australian reader, Mr. Hamilton Grapes, A.M.I.A.E., adviser on motor matters to the G.P.O., Wellington, N.Z., sends us some notes regarding the needs of Overseas riders in motor cycle design. He infers that the small solo machine would enjoy but a limited demand, and would mainly be used for work in the towns. The two-speed clutch machine of medium weight, preferably the opposed twin, is growing in popularity, and should have an engine of 270 c.c. to 350 c.c., and be equipped with 26in. × 2½in. tyres.

It is most important that such machines should be economical in petrol and oil, and should be capable of obtaining the greatest possible mileage before it is necessary to lay them up for overhaul. Such machines are not required for actual touring purposes. For the solo machine for touring purposes our correspondent suggests a cubical capacity between the above and the 1,000 c.c. sidecar machine. The latter, he states, is not adapted to touring purposes in the hands of the ordinary rider, owing to its excessive weight and uncontrollability.

He emphasises that the solo machine should possess lightness and a high efficiency power unit, and he states that there exists a strong objection in Australia on the part of the buying public to the heavy weight machine for solo work.

A three-speed gear box and clutch with ample friction surface are most necessary. The delicacy of clutch adjustment, as arranged for on American machines, has made, Mr. Hamilton tells us, the Indian greatly appreciated. A spring frame is desirable, if possible, without too many small pivoted bearings, which the average rider will not take the necessary care to lubricate.



Australians with their travelling workshops passing through a military centre in England. Repairs of all kinds are undertaken by these travelling depots, which have proved highly valuable.

The saddle position and the centre of gravity of the machine should be low, and the saddle should be arranged so that the rider sits *in* instead of *on* the machine, and well forward so as to ensure immunity from rear wheel shocks. The rearward and high saddle positions on present motor cycles are considered by many users Overseas as objectionable, and Mr. Grapes specially emphasises the importance of the fact that spring frame arrangements must possess great lateral rigidity, while an electric lighting equipment is desirable if compatible with reasonable weight. He also lays great stress upon the necessity of the machine having a pleasing appearance.

* * *

Ground Clearance, Mudguarding, and Frame Design. Our correspondent then goes on to raise an interesting point. We have always had it dinned into our ears that motor cycles for Overseas use should possess a high ground clearance. This, he points out, is incompatible with the essential low centre of gravity, and it is even therefore more mythical than real, except in a few notable cases in which the clearance is too low for use. On Dominion highways a clearance of 4½-5in. is considered to be ample for prevailing conditions, owing to the rapid improvement of the roads.

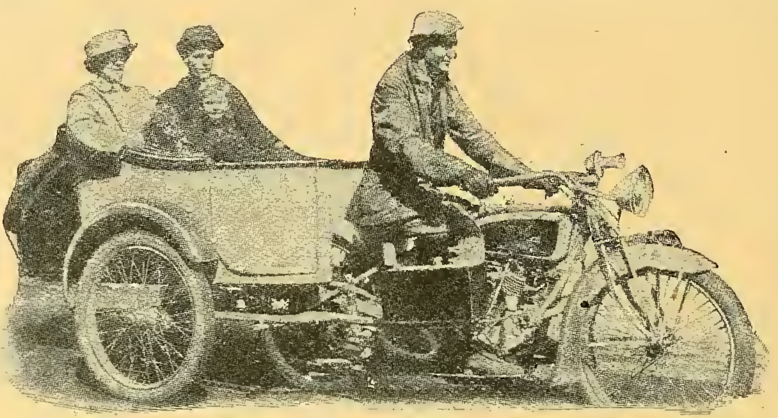
If rear springing is not adopted, 28in. × 3in. tyres are essential. Abnormal mudguard clearances have not been found effective in preventing clogging when weather conditions are severe, and these, he goes on to say, mitigate against the low saddle position. A clearance of about 1½in. only is most suitable, and anything over this serves no useful purpose. It is especially important that Overseas machines should have a petrol capacity of 2½ gallons, and carry half a gallon of oil.

Folding footboards should be fitted instead of the rigid ones to be found on most English machines. Our correspondent also suggests that an easily detachable

Overseas Section.—

shield, fixed to the down front tube and attached to each footboard, would be most desirable for wet weather, and would be much appreciated

It is interesting to note that Overseas the value of the automatic carburetter is being realised to an increasing extent. The Schebler carburetter, fitted to so many American machines, is proving highly satisfactory, and gives excellent results even with the heavy grade fuels now in use. As regards controls, the twist grip pattern, in combination with Bowden control, is considered to be ideal.



A type of passenger motor cycle becoming increasingly popular in the States. Although it is capable of carrying a big load more comfortably than a sidecar, British motor cyclists have not as yet shown any great enthusiasm for it. Even so it would be rash to prophesy that in the near future it will not be used in this country.

It is pointed out that the main weakness of pre-war engines was the connecting rod bearings, the big end surfaces of which were inadequate, while the removal of cylinders should be facilitated by other means than the high tank bar clearance. The adoption of a method such as a detachable tank bar, as on the old Humber machine, or an off-set bar like the Zenith, would be highly appreciated, and would incidentally facilitate low-set design.

Another interesting point is that our correspondent speaks with great enthusiasm concerning mechanical lubrication on motor cycle engines, as many drivers do not give their engines enough oil when using the hand pump owing to lack of necessary knowledge. Much oil is needed owing to the excessive heat in the Dominions during the summer and the excess of low gear work and slow running.

Our informant concludes by saying, "Finally, I am firmly of the opinion that if these desiderata were incorporated in the design of the best British machines, the British manufacturers would be able to recapture and hold the market in the Dominion of New Zealand, as well as in Australia.

New Zealanders for Motor Cycle Sections. A New Zealand motorist who joined the Army with the object of being a despatch rider (presumably in the A.S.C.) was, owing to too high a medical category, enlisted in the infantry. He writes to us, "I would like to point out the utter futility on the part of intending Overseas motorists of anticipating obtaining a transfer to the M.T. Corps should they leave their respective countries for active service at the Front. The conditions which have to be complied with render the intending motor despatch rider's transfer a practical impossibility. Publication of matter relating to this particular subject will undoubtedly avoid a great many disappointments in the future should the war continue for much longer; and, as I have a great number of personal acquaintances in New Zealand who are prominent motorists and are readers of your valuable journal, and who anticipate joining up in the M.T. section, this may be a means of advising them on the matter, and therefore minimise the chances of their being disappointed in their desires."

Our correspondent seems to be unaware of the fact that men are now only accepted for the M.T. who are below Class A, or who are in a comparatively low medical category. Despatch riders, however, for the Royal Engineers (Signal Section) and for the Royal Flying Corps must be Class A men, but, unless there are vacancies in these particular corps, and unless recruits have special knowledge and experience of motor cycles which would qualify them to become Army motor cyclists, they will be placed probably in the infantry. Transfers from one corps to another are not looked upon with favour by the Army authorities.

A Selection of Letters from Readers scattered all over the World.

Softening the Drive.

Mr. D. Sharp, of Pucklechurch, Bristol, writes: "In the 'Overseas Section' of December 27th issue I observe that Mr. William Coultas complains of breaking spokes on his 4¼ h.p. B.S.A., chain drive. Let him extract the compression and depression shock springs contained in the cush drive and insert rubber buffers. If he cannot obtain rubber of sufficient thickness, etc., he can extemporise with strips cut from an old tyre. The rubber improves the 'drive' and gives smoother running. Since scrapping the B.S.A. springs and using rubber cushions I have not broken a single spoke in my back wheel. Before doing so I broke spokes constantly."

Roads in N.S.W.

Colin A. Cruwys writes to us as follows *re* road conditions and suitable machines in his part of the country: "In your edition of October 25th, 1917, I noticed two photographs headed 'Roads in Australia,' and a statement to the effect that they are a sample of the roads to be found near Bankstown or Liverpool, N.S.W. Any ordinary person reading Mr. Sydney Turnbull's letter would take it for granted, judging from the photographs, that they were the normal road conditions. That is not so. I have lived around that district for the last twenty-two years, and I have not yet seen any part of the road between Sydney or Liverpool in such a condition, unless it were on some back bush track. I take it for granted that the photographs are part of the main road, and I think that Mr. Turnbull has slightly exaggerated things.

"About English machines not being on the Australian market, I think he is wrong; there are very few English cycles that are not on the Australian market. I do not agree with him about American machines, which are not as heavy as the average English machine, and I do not think that they suit our road conditions. I rode a Triumph for some years, and encountered no trouble. I agree with him

Overseas Section.—

about the mudguards. They do need more clearance. I have met with mudguard trouble both in England and France, so that it does not apply only to Australia.

"I am now with the Australian Expeditionary Forces as a cyclist. I think that any other ex-Sydney cyclist who sees the photographs will agree with me."

British Machines in the Colonies.

MR. R. G. FOOT, Blairmore, Alberta, Canada: "I value *The Motor Cycle* highly, and it has been especially interesting since the views of Overseas subscribers were placed in it, as it gives one the feeling that many at home are waking up to the vast undeveloped possibilities of the Colonies. As most of the men put it, we would ride British machines, only we cannot get them; therefore we are glad to get American, which control the market, and are built for Colonial conditions."

Which Type of Control?

MR. W. B. SMITHSON, of Toronto City, writes with reference to a recent controversy: "I have been much interested in the discussion on the most desirable types of controls—outside levers or inverted. If we are to have Bowden wires, then for goodness sake let us have them *outside*, so that we can get at them to oil the inside cables, easily renew them if necessary, and take out the handle-bars (which is often necessary) without unnecessary labour. But—why have wires at all? They rust, break, trap, and are a source of endless trouble. What has become of the old Vindec Special rod control? Could not the same idea, in the light of modern manufacture, be effectively applied? I abominate twist grip controls, except for the contact breaker, as they are insufficiently delicate for carburetter manipulation, but twisting rods might easily be operated by handle-bar levers."

A Reply to Mr. Warne.

"W.G.," with reference to Canadian business, writes: "Mr. W. R. Warne, in his letter published in the Overseas Number for October 25th, 1917, shows a lack of knowledge regarding the difficulties that agents for English motor cycles are up against in Canada, and especially at the present time when 'spares' cannot be procured, not to mention machines. I have been in Toronto selling English goods for thirteen years, viz., Rex, Brown, and Triumph. Mr. Warne states that 'the Americans monopolise the whole business, that their machines are running about in thousands.' Last year I rode over 4,500 miles on a 4 h.p. Triumph, S.A. hub gear, and a Junior, and rode more or less almost every day, including most of the winter. My rides vary from ten to 100 miles. In a ride of fifty miles I do not meet half a dozen American machines. Mr. Warne remarks about the Toronto police riding Hendersons, but he does not give the reason, viz., that they could not get Triumphs because the makers could not supply.

"Another statement Mr. Warne makes is that Triumphs are looked upon as only fit for city use. If he will take his memory back a few years to the three days' reliability run held by the Toronto Motor Cycle Club he may remember that some sixty or seventy riders started—the distance about 250 miles. Two Triumphs only entered, and they won the first and second prizes—that is, the solo and sidecar events. No other machine made full marks.

"As Mr. Warne states, 'the man who owns an Old Country machine has to struggle by taking care of his own requirements as best he can.' I know a place in Toronto to-day where there are over 500 dollars worth of parts for Triumphs. Mr. Warne gives a very bad impression about the English machines, so he swears by the American article. If this is warrantable, why does Mr. Warne advertise in a Toronto paper the following: 'Wanted, Triumph motor cycle, three-speed model preferred, must be in perfect mechanical condition.—State full particulars, price, date of model, equipment, etc., to WARNE' Then follows Mr. Warne's Toronto address.

"There are over 130 Triumphs in the city, and I think if he will read page 426 in *The Motor Cycle* for November 1st, 1917, he will change his idea of the Triumph only being fit for city use. Where the 8 h.p. twin scores is its ability to lose 2 h.p. and still get through; but the Triumph rider, if he loses 1 h.p., is up against it under severe conditions. But, put the latter machine into a man's hands who can keep it in tune, and it will show its back number to the 'twin' every time, especially if the owner of the 'twin' has not the skill to look after his machine.

"When the English makers can put on the Canadian market a machine as reliable and good as they manufacture at present at a price that the American machine sells for here then they will have a chance of a good market, and there will be plenty of agents to push the goods. I have an idea that some of the English makers have lost money in their attempts to foster Canadian trade."

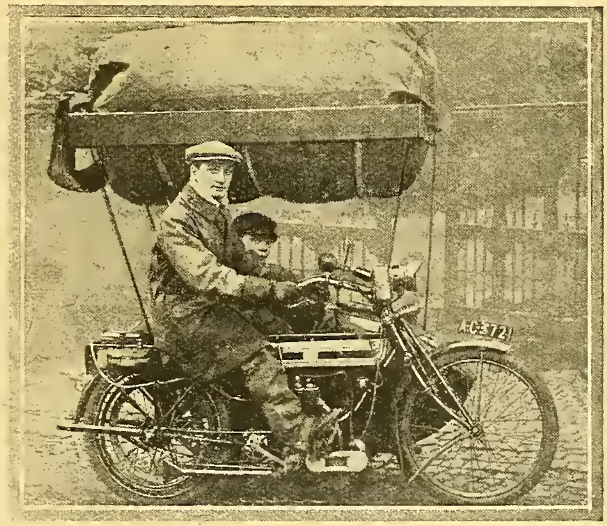
Cheaper Machines Wanted.

MR. THOMAS H. BLAKE, of Cottesloe, West Australia, writes: "I thoroughly enjoy reading your excellent journal. The letters *re* trade between Australia and England are very interesting. Unfortunately, owing to the war, the Overseas trade is passing into other hands—temporarily only I hope. If the English trade would produce a cheaper machine the market would increase enormously, but we must have spring frame machines for Australian roads."

Some Remarks from the Cape on British Machines for Overseas.

MR. HATTON writes us from Cape Town on machines for his country as follows: "Personally, I think there are only two considerations in the design of a colonial machine which can be given positions of primary importance. These are weight and accessibility. So long as the weight is reasonable I would prefer a 6 h.p. twin to a 3 h.p. single, but if I have to gain the extra power by an acquisition of extra weight, then I will go without the power and be content with a really good 2 h.p. single-cylinder lightweight. It is only a question of gearing when all is said and done, and a suitably geared 2 h.p. will follow the big twin anywhere, though the converse is not by any means true. Get some of your heavyweight enthusiasts to get stuck in real sand, and then ask them if they really think the heavyweight a better all-round machine than the lightweight.

"Accessibility has been so laboured and so discussed that I feel almost ashamed to bring it forward again, but really, as long as English manufacturers are proud of their pig-headed conceit, it seems to me the only method likely to make them consider the advisability of a change in tone. If they will not change their methods, perhaps they will also object to changing their turnover, and so will not mind losing 'the dibs' as a consequence. Once again I say 'Accessibility,' and, if anyone does not know what I mean, let him turn to the making of matches or margarine; he is certainly not intended for a motor cycle manufacturer."



A 4 h.p. Triumph outfit fitted with a Robin Hood gas holder, the property of V. G. Mutton, of 44, Rectory Road, Redditch. It will be noticed that the gas holder rests on webbing suspended from a wooden tray, which is supported by four steel supports from the sidecar chassis. It is possible to fill the bag from a 2in. gas main in one minute and a half, obtaining sufficient gas to run with sidecar and passenger approximately sixteen miles.

Women Drivers for Government Motors.

Many ladies have shown interest in our recent paragraphs on the subject of the need for drivers for Government vehicles, and it is clear that many have been prevented from offering their services simply through lack of information and knowledge of how to set about it. As we stated in our last issue, all women drivers for home service are obtained from the Women's Legion.

This organisation has for several months past provided a regular supply of drivers for the R.F.C. and the A.S.C., and is now in urgent need of recruits, who should have some knowledge of driving, but need not be highly skilled.

The Standard Necessary for Recruits.

Recruits will be furnished with instruction, provided they have some groundwork on which instruction may be based. Any woman who can handle a car on the road need have no fear of offering her services, even though she has little idea as to *why* the car goes faster when she presses on the "little pedal between the two large ones." She must be capable, however, of swinging her own engine.

The Physical Standard.

The case of physical fitness is most important, as "soft jobs" are at a discount, but the work is not only healthy, but health-giving, even if strenuous.

Practically all the work is in the country, and long journeys are very common. The usual hours are 8 a.m. to 6 p.m. The normal leave is thirty-six days per year.

The Main Question and Uniform.

Pay is 35s. weekly, with 5d. an hour overtime, while superintendents receive 52s. 6d. weekly. Drivers have to keep themselves, but special hostels and food at army rates are available. One complete outfit per annum is provided for each driver.

The recruit must produce two references, pass an elementary driving test, and undergo a maximum of one month's probation at a salary of 25s. per week.

A promising recruit stands a fair chance of becoming an inspector at 40s. per week.

The majority of the vehicles are standard touring chassis fitted with van bodies, but some are sidecar combinations.

The National War Funds.

The National Relief Fund (distributed £3,743,877)	£6,324,423	0	0
British Red Cross Fund ..	8,917,243	15	0½
Tobacco Fund	147,454	0	0

Standardised Bicycle for U.S. Army.

Standardisation in all things has long been the agitation of the English technical press, but in America standardisation has for much longer been the manufacturers' achievement. The U.S. Government has now adopted a standard push-cycle—to wit, the Liberty—which is to be made by several leading cycle manufacturing firms.

Motor Cyclist on Tractor Work.

We reproduce below a photograph of Mr. R. P. Ravenhill, manager, Messrs. Fryer's No. 2 Garage, at Hereford, an engineer responsible for the Hereford unit of tractors working under the Food Production Department. Mr. Ravenhill often used to go in for competitions prior to the war, and won a good many medals on a 3½ h.p. Rover. He has been twice rejected for the army. The motor cycle garage with which he was formerly connected is now entirely devoted to agricultural tractors running under his direction, and one of these has accomplished the very fine performance of forty-eight acres in one week under the Government scheme.

Mr. R. P. Ravenhill, who has control of the Hereford unit of tractors working under the Food Production Department.

SPECIAL FEATURES.

1918 MODELS.

THE DYNAMICS OF BICYCLE LOCOMOTION.

MOTOR CYCLE AND MOTOR CAR RESEARCH.

American Navy Enlists Motor Cyclists.

It was quite in the early days of the war that the Royal Naval Air Service enlisted car and motor cycle drivers, who earned the sarcastic pseudonym of "deep sea chauffeurs." Now we learn that the U.S. Navy Air Corps needs motor cyclists as first and second-class petty officers.

A Motor Cyclist Signalman.

Schuetz, who is a motor cyclist enthusiast, and a signaller in the U.S. Army Machine Gun Battalion, has become so expert in the Morse code that he can signal while riding his machine with his hands off the handlebars. He declares he will take his motor cycle to the Front with him, and even go "over the top" mounted on his faithful machine.

Petrol in Stock.

We are often asked by readers what they may do with the petrol they have in stock, having purchased it before November 1st. The following answer is from the columns of our sister journal, *The Light Car:*

"The Petroleum Pool Board Distribution Committee has agreed to instruct all garages to buy back from their customers, on request, any motor spirit stocks which they may hold at 3d. per gallon below the wholesale price on the date of the transaction. At current price this represents a loss of 8½d. per gallon, made up as follows:

"The present wholesale price is 3s. 0½d., and the retail price 3s. 6d. Threepence less than the wholesale price is 2s. 9½d., so that anyone selling back his stock stands to lose the difference between 2s. 9½d. and 3s. 6d., viz., 8½d. With the exception of a very few who may have stocks by them, purchased some time ago, who would not lose so much owing to the then lower retail price, we imagine, that the majority will hold their stocks.

"WILL THE DUTY BE REFUNDED?

"Then there is the 6d. per gallon duty paid previous to the time of purchase, and apparently not recoverable, unless the Petrol Control Committee will accept the garage proprietor's endorsement on the licence coupon that the motor spirit has been brought back. What has the Petrol Control Committee and the Pool Board to say with regard to this point?"

he Association of British Motor and Allied Manufacturers.

The council of the above body has ecently received an additional member n the person of Mr. H. C. B. Underdown. dr. Underdown is the chairman and nanaging director of Commercial Cars, td., of Luton, and also chairman of he Commercial Vehicles Section of the .B.M.A.M.

inance and the Magneto.

At the general meeting of shareholders f Messrs. Simms Motor Units, Ltd., ecently held, it was decided to declare dividend of 25% of the paid-up capital f the company, to transfer the amount f £4,000 to reserve account, and to carry orward a balance of £33,757 15s. 6d. to he next account.

or Amateur Designers.

We observe that Mr. C. Binks, of hœnix Works, Eccles, is offering a prize or the best kick starter design sent to im, and no doubt a good many of the mateur designers from whom we regurly hear, and from whom we are always lad to hear, will be weighing in with heir ideas.

uccessful Appeal against Petrol Conviction.

At the Birmingham Quarter Sessions ast week, a motor cyclist appealed gainst a conviction registered against im on December 3rd, 1917, for illegal se of petrol. The appellant was repre-ented by the A.A., and was successful getting the sentence quashed. The lleged offence took place on November 8th, 1917, and in the magisterial court he defendant had been fined £4, or in efault twenty-one days' imprisonment. ho defendant, by the way, was Mr. ouster, an ex-champion cyclist, well nown some years ago in Midland cycling ircles.

otor Cycle Postmen.

Motor cycles are being used for the ollection and delivery of mails in oboken, New Jersey, and four Harley-avidson motor cycles and sidecars are eing employed in this manner. The ew method is expected to effect a onderful saving in time and labour so r as the collection and distribution of tters are concerned. Hoboken is one the first states in the U.S. to adopt e motor cycle as a means of helping e post-office.

ore Petrol?

We refer in our leader this week to e hope entertained by some motorists an early alleviation, if not settlement, the fuel crisis. Perhaps the most cheerful idiot" of this type that we ve met up to the present is the man ho is spreading a rumour, in which he plicitly believes, that the existing rerictions are to be waived for every eek-end during the summer months, so at the poor munition worker, about hose troubles we have recently heard so uch, may have a week-end's joy-riding! Some people are actually believing him, d we have had more than one querist king us if there is any truth in the mour. We take this opportunity of suring every reader that, as far as e are aware, the rumour is entirely void of any foundation in fact.

Yankee Compliment to a Britisher.

Indian, Wells, and Franklin are names that always ran together in the pre-war motor cyclists' ears. Mr. Wells informs us that his *confrère*, Mr. C. B. Franklin, late manager of the Indian Dublin branch, has been at the Indian factory for the last fourteen months, and has just been highly complimented by being nominated by the U.S. Government as one of the five engineers on the Standards Board, erected for the purpose of designing and getting out a standard army motor cycle.

The Motor Cycle in Sweden.

We have received the following news from a Swedish correspondent: "We have a dull time now in the motor world; all pleasure motoring has been abandoned, and all one is allowed is riding for testing purposes, and that to a very limited extent. We are resting in the Swedish Motor Cycle Club, Stockholm, where old friends from our pre-war competitions and trials often gather together. I have spent quite a long time in the club. We have very nice, cosy premises, and here we are lying on sofas in the smoking room in Oriental style, smoking and dreaming about the happy days before the war and of still happier times to come when peace arrives."

Selling Motor Cycles to U.S. Soldiers.

We extract the two following paragraphs from *Motor Cycle and Bicycle Illustrated* (New York): "Sales of Indian motor cycles among the 30,000 soldiers stationed at Camp Bowie, near Fort Worth, Texas, are being promoted through a well organised campaign conducted by the local supply company. Its chief feature consists of spectacular stunts to attract the attention of the men in khaki. Through these performances the sales force gets into personal touch with the soldiers interested. Little difficulty is encountered in closing with a soldier who shows sufficient interest to ask for particulars as to price and terms."

An "Aviation Stunt."

"One of the things which has attracted the attention of many prospective purchasers is the 'aviation stunt,' the specialty of O. L. Locklear, who is in charge of the mechanical department of the Burton agency. A 12in. board is arranged on supports at a 30° slant, with one end touching the ground and the other end elevated about 18in. The rider drives his machine on to the board at high speed, and as they leave the far end machine and rider sail through the air as high as 8ft., making a leap of about 60ft. before coming to earth."

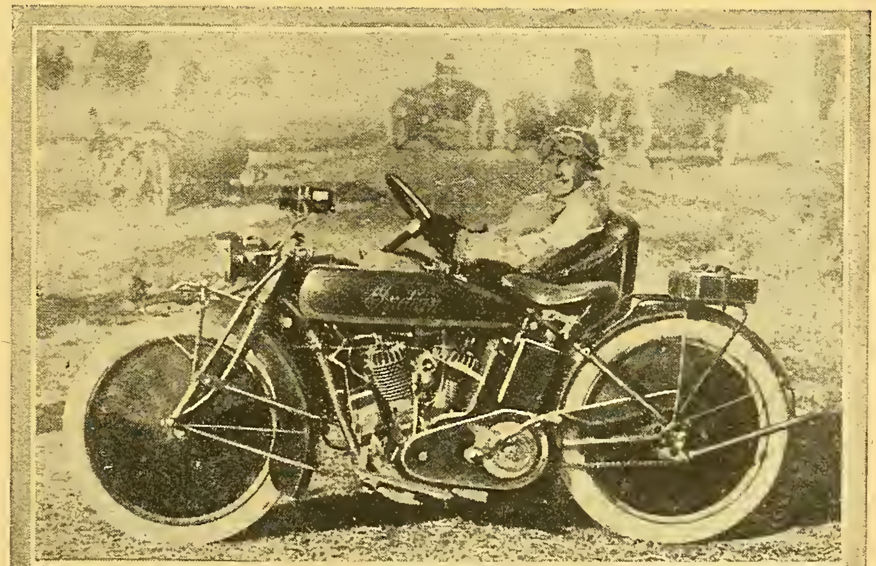
Some Taxi Restrictions.

The privileges enjoyed by taxis while all other motors enjoyed nothing but restrictions have long been a sore point with the private owner of car or cycle. Now, by a recent Order, the taxi is restricted in its operations to the area in which it is licensed to ply and three miles beyond.

The Greatest Reliability Trial.

Several times in these pages we have referred to the war as being the greatest reliability trial for motor vehicles ever held. Capt. Constant, an American motor cyclist, holds the same opinion, and wrote recently to an American contemporary the following letter: "Tell those birds who are wasting paper in your sheet *re* "The Best Endurance Run" to close up, as we have the best endurance run ever pulled off right here, and we can prove it to them if they will take the trouble to step in the nearest Recruiting Office. Tell them to sign up, and come on over; we will prove it to them, and it won't cost them a cent for transportation."

"Some" sense, "sure"!



MOTOR CYCLING IN LUXURY.

An Indian sidecar owned by a Spanish motor cyclist. He has fitted it with wheel steering, and drives from the sidecar seat. The controls for throttle and spark, brake, and clutch are inside the car. The finish of the outfit is enhanced by the fitting of disc wheels.

THE DYNAMICS OF BICYCLE LOCOMOTION.

The Question of Static and Dynamic Equilibrium.

LIKE the much-discussed problem of the squirrel on the pole, the problem of how the bicyclist maintains his balance by steering is one that may lead to endless discussion unless attacked from first principles. I have read with the greatest possible interest the numerous letters in *The Motor Cycle* on the subject. It is not difficult to discern that the writers have neglected the study of rigid dynamics—a very difficult subject, I admit—but one of immense importance to those who are interested in such apparently simple problems as the one in question. In the first place, your readers must keep distinct in their minds the two totally different problems involved by those of (*a*) dynamic and (*b*) static equilibrium. By (*a*) is meant the preservation of the balance of a body in motion, by (*b*) that of a body at rest. To take a simple example—the bob of a pendulum is in static equilibrium when the string or rod is perpendicular. It is in dynamic equilibrium when describing a circle at uniform speed. In both cases the string is in tension, and in the latter case, if there were no friction, the body would continue to travel in that circle *in æternum.*

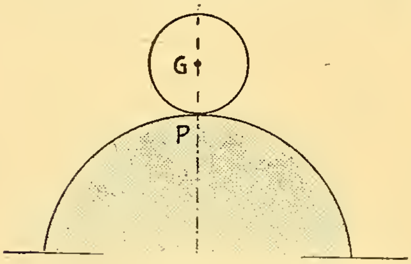


Fig. 1.

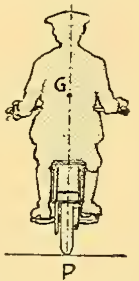

Fig. 2.

The finest example of a body in equilibrium and in motion is the earth or one of the planets revolving round the sun. We may go further and say that if the body be disturbed by an external impressed force acting for a certain period it will return to its state of equilibrium, provided the system is undamaged. We can conceive of an enormous meteor, say 100,000 tons, striking the earth, causing a local fracture, perhaps, but leaving the system unaffected, and the earth would continue its hustling progress round the sun.

Equilibrium.

Now let us apply this to the bicycle (1) at rest. Just like a billiard ball on a sphere (fig. 1), the cyclist and machine (fig. 2) are in a state of *unstable* equilibrium, because the slightest imaginable movement on the part of the sphere or rider will tend to cause the centre of gravity G to fall outside the point of support P and upset the balance.

This problem must be kept entirely distinct from that of the bicycle (2) *in motion.* First of all get rid of ideas of centrifugal force, gyrostatic action, circular motion, etc. Let us get down to simple first principles. The bicycle is a mechanical contrivance designed entirely for locomotion. Imagine a rider on a straight road. We have said that a body will be in a state of stable dynamic equilibrium if travelling in a straight line and does not require an external impressed force to maintain it in that state of motion. Now a bicycle is so constructed that *when in motion in a straight line, if it is attempted to induce it to leave the straight line, forces are immediately set up which cause it to return to that line.* This is the whole crux of the matter. When the cyclist moves along the line AB, and by a deflection of the handle-bar changes his position to C_1D_1 from CD (fig. 3), a force is set up acting perpendicularly through G, tending to right the machine and keep it in the straight line. This force is not necessarily brought into play unless the cyclist leaves the straight line.

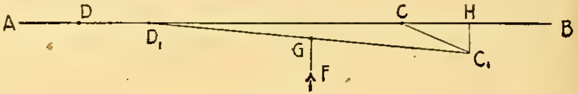

Fig. 3.

That is dynamic equilibrium, and that is the point missed by these critics. They are looking for a force that is not there, because it is an axiom in rigid dynamics that the body will be in equilibrium provided that, when it tends to leave the straight line, forces are immediately set up to cause it to return, and so it does not leave the line unless by a deliberate effort on the part of the rider. If the earth were to depart from its path *ever so little, enormous* centrifugal force would be brought into play to cause it to return to its path. The force F is so *great* for a *small* deflection C_1H that its ratio is infinite, and the body persists in its state of motion. This explains why a cyclist can ride "hands off" in a straight line.

Cornering.

Now take a cyclist rounding a corner. Here, then, is a steady deflection of the line, and therefore a steady force exerted through G (fig. 4). How is the equilibrium maintained?

Well, the rider subconsciously banks his machine until the force of gravity just balances the force F caused by the

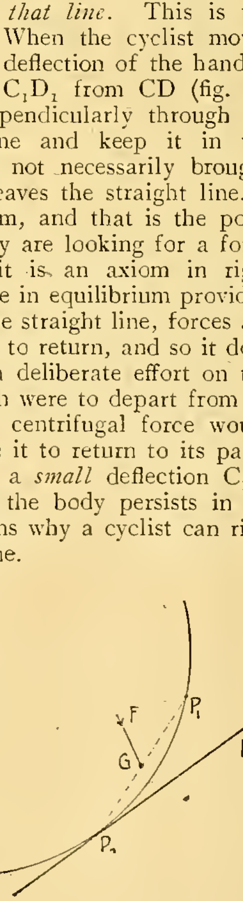

Fig. 4.

The Dynamics of Bicycle Locomotion.—

deflection from the line. How, then, are we going to classify the force F? Is it gyroscopic? Certainly not. Is it centrifugal? It can hardly be so, since it acts at right angles to the plane on which the circle is described. It is a force peculiar to the bicycle. It is called into being only when the path of the cycle departs from a straight line. A very little thinking will show how it is set up.

Suppose P to move from the straight line to a short distance to P_1, P_2 will also move, but it will be infinitesimal compared with P. Now what has happened to G? It has fallen to one side of P_1P_2, the line of support, and hence tends to cause the equilibrium to be restored. The force F then is none other than that of gravity. What else, after all, could it be for a cyclist on a straight, level road? When a cyclist is rounding a curve he simply banks the machine in order to bring G into line with P_1 and P_2. What part does centrifugal force play? It simply tends to increase the banking slightly. (Compare a railway engine where the banking of the outer line is unnecessary below certain speeds.) What part does gyroscopic action play? Very little. I ride a three-speed hub heavyweight scaling 170 lb. The back wheel of this is very heavy. Yet the steering is affected more by the *weight* of the rear portion of the machine than by the gyroscopic action, which is very little except at high speeds, the weight being chiefly concentrated in the hub.

Stability.

The whole problem of balance, neglecting considerations of centrifugal force, gyroscopic action, etc., is well illustrated from sculling. The light river "toothpick," so common in peace-time on the river at Oxford, is quite unstable when at rest, but when in motion the pressure of the water on the sides of the boat tends to prevent the sculler's body from departing from the vertical. At low speeds this is inadequate, just as it is in the case of the aeroplane.

In working out the stability of an aeroplane it is usual to ascertain whether the oscillations about the equilibrium position are sufficiently "damped" to justify it being classed as "stable." But in practice the machine at high speeds rides quite steadily except under exceptional circumstances. The same applies to the bicycle in motion. When the rider of a machine has learnt to trust to its inherent stability and be guided by it, he and the machine become, as it were, one unit, and as long as the wheels keep the road he is absolutely as safe as the earth on which he spins.

W ARTHUR JONES, B.A., M.Sc. (Oxon.)

Motor Cycle and Motor Car Research.

The Question of Forming a Trade Association for Research Purposes.

THE whole question of research work as applied to the motor industry is at present very much to the fore, and the motor cycle manufacturers may claim considerable credit for having been the first section of the industry to take this matter up seriously. Probably it will be found in their case, as in others, that the simplest and best procedure is to form a research association on the lines indicated by the Research Department. One of the great advantages of doing this is that it practically ensures a substantial Government grant.

It would be fairly safe to assume that the motor industry will probably not be long in following the example of the motor cyclist industry in forming a research association. It will be a good thing if the constitutions of these two associations could be in essence identical. This would make collaboration easier on the many occasions when it will no doubt be desirable. The problems with which the motor cycle industry is faced are not identical with the most obviously necessary research activities of the motor industry. It is inconceivable, however, that the two will never overlap. Many engine researches, for example, must be of almost equal interest to both, and the same applies to many researches into materials suited for use in engines and other parts. In other respects the research of the motor cycle industry can be combined perhaps more conveniently with that of the cycle industry. I am not suggesting that an attempt should be made to create one research association to cover motor cars and vehicles as well as cycles and motor cycles. What I do suggest is that it will be well to recognise in advance the certainty that all these will wish to collaborate at one time or another. If the constitutions of the various research associations, so situated, are in broad outline identical, and the basis of subscription is similar in each case, then collaboration and joint expenditure will be much more easily arranged.

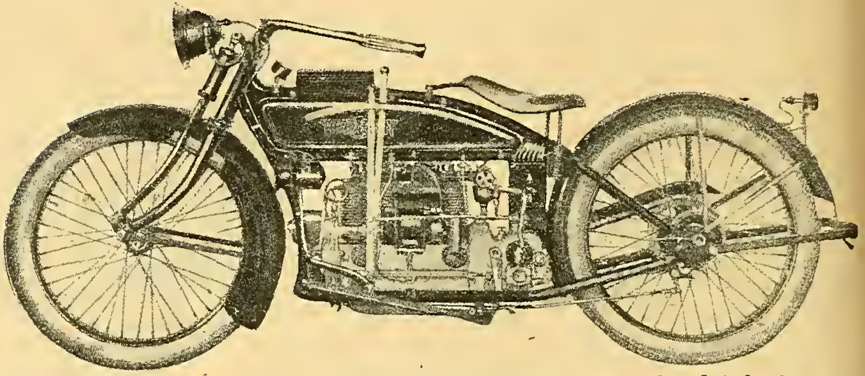
A Splendid Opportunity.

The next point to be emphasised is that we now have a heaven-sent opportunity of conducting useful research at a comparatively low cost to the industry. Up to a certain considerable figure, the Research Department will generally subscribe one pound for each pound subscribed by the manufacturing members of a research association. In other words, the Government pays half the cost of the research while the industry gets practically the whole of the benefit. Moreover, the manufacturer's subscription is paid out of income. Were it not used for research, it would not all represent profit. Some of it would certainly go in income tax. In many cases, still more would go towards the payment of Excess Profits Duty. Thus in effect the Government is really offering to bear a good deal more than half the total cost of research work. The inducement to the manufacturer is great, and if this opportunity is not accepted the industry will lose a magnificent chance of pushing ahead of its competitors in other countries.

Undoubtedly there are many firms that will readily recognise this position. Consequently, the last point I wish to make is that the thing should be absolutely unanimous. Those who stand out, if any do so, will be sorry later on, when the research begins to bring results in which they are not permitted to participate. The original members of the research association will no doubt take care that those who want to come in later, when the work has already borne fruit, shall have to pay very substantially for the privilege. W.H.

THE HENDERSON ELECTRICALLY-EQUIPPED MODEL.

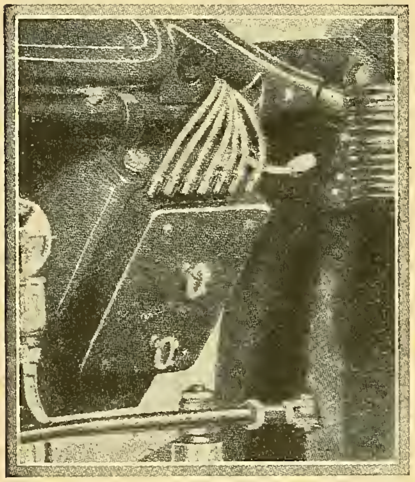
Particulars of the New Henderson Electrical Model, embodying Separate Generators for Ignition and Lighting Purposes.



The 1918 electrically-equipped model four-cylinder Henderson motor cycle. It is fitted with an engine of 778 c.c. and a three-speed gear.

IT has for some time been common knowledge that an electrically-equipped Henderson model was shortly to be put on the market, and detailed particulars have been awaited with interest.

The design of this model is particularly commendable, in our opinion, in that the extra fittings have not in any way injured the general proportions of the machine, which we described on November 15th, 1917, nor do they protrude as if they were casual afterthoughts thrown on and fastened in any odd position.



Showing how the battery can be swung to one side to allow the engine to be entirely removed from the frame without disturbing the wiring or dismantling any part of the electrical system.

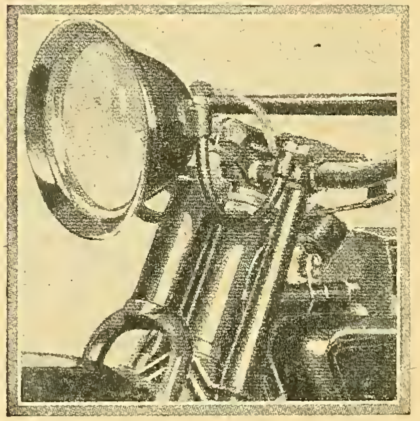
The high-tension magneto for engine ignition purposes is retained, and the generator for accumulator charging occupies a position similar to that normally taken by the magneto in English machines, viz., in front of the engine. It will be seen that the generator is a very compact piece of work, and as it equipped as an integral part of the motor, the question of drive has been very easily and neatly solved. It is driven by a shaft from the timing gears, which is both large and strong enough to ensure long life and reliability. The commutator is mounted on a half-inch shaft running on ball bearings, and has been designed with accessibility kept well to the fore. The commutator indeed may be removed after two screws have been taken out. All that is necessary in the way of lubrication is the replenishment of grease in the front cap about once a year.

Control and the Storage Battery.

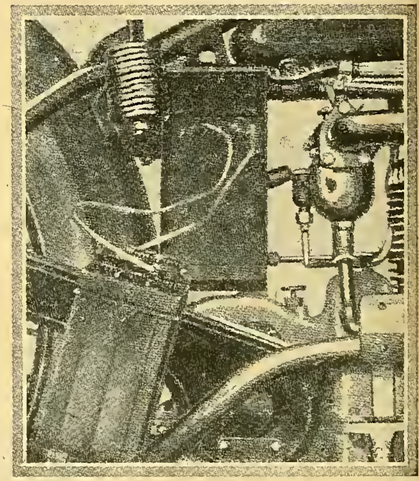
The control of the output of current by the generator is by means of a hand-operated switch. When this switch is in the "off" position the generator is obviously running free, and we are assured that when the generator is not working under load it absorbs practically no engine power, so that this model Henderson is as fast as the ordinary standard model.

The storage battery is carried underneath the saddle, and, as may be seen from the illustrations of the complete machine, is very neatly stowed away. The illustration of the storage battery itself shows how this may be swung out of the way so as to allow of access to the engine when this is necessary. Another interesting point about the battery is that it may be removed complete from its case without necessitating the disturbance of any connections. The battery is shown removed in our second illustration.

The head lamp is of the two-bulb pattern, a small bulb being fitted for use when the machine is standing, or whenever a powerful head light is not necessary, and, of course, it effects a saving in current. Only a single wire is used to feed the head lamp, the return circuit being by way of the frame, but provision is made for the fitting of a sidecar lamp, should this be necessary, by a double socket switch, one plug of which feeds the tail lamp, while the other is for the sidecar or a hand inspection lamp. The horn is also part of the equipment, and is fitted on the tube under the tank, immediately above the generator.



The head lamp, with the substantial carrying arms, and the current indicator mounted on the top tube in front of the tool box.

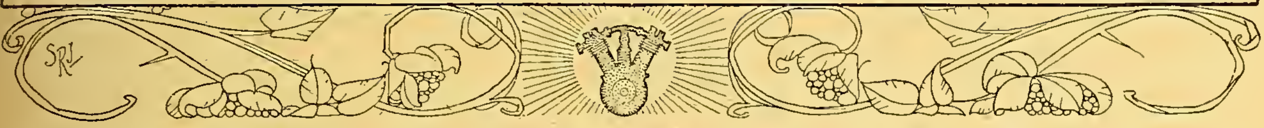


The batteries may be removed without disturbing any connections.

Wiring and Detail Arrangements.

The wiring and switch details have been carried out with the greatest attention to detail, and also include that very valuable asset, a fuse box. A fuse box is a fitting only too often omitted from far more elaborate lighting sets than the Henderson, and its absence has sometimes given rise to serious trouble. A current indicator, or ammeter, is fitted on the top frame tube near the steering head, and may be seen in the illustration of the complete machine immediately in front of the tool box. The extra price for this equipment in America is approximately £10.

BORING CYLINDERS & MAKING PISTONS.



Some Hints on an Undertaking generally handed over to the Expert.

READERS of *The Motor Cycle* have often made enquiries respecting the boring out of cylinders, therefore a few hints may be acceptable.

Before the work is undertaken it is well to grasp the fact that accuracy to $\frac{1}{1000}$ of an inch is necessary. The boring out of a cylinder usually necessitates the fitting of a new piston, which should be as nearly as possible of the same weight as the old one, and as times are not normal, and there will probably be some difficulty in obtaining a suitable casting, I will give some directions for the guidance of those wishing to make patterns and have pistons cut.

How to Make Patterns.

In making patterns use some close-grained timber, such as beech, or yellow pine, or sycamore. Take a small block an inch or so longer than the intended piston and round it roughly with a chisel; bore out the centre to form a rough cylinder much smaller internally and considerably larger externally than the piston. Fix this block in the lathe either by chucking it or attaching it to the face plate by four screws; turn up the outside a little larger than the required piston, say $\frac{1}{8}$in. all round. Next bore out the inside, making it very slightly smaller in diameter ($\frac{1}{32}$in.) than the inside of the old piston, finish with fine glass paper both inside and outside, cut the skirt dead true, and mark where the centre of the gudgeon pin will be; finally, cut off so that you have a perfect cylinder exactly the same length, or perhaps $\frac{1}{16}$in. longer than the length of the old piston, measuring from the skirt to the underside of the piston head. Now cut a disc about $\frac{1}{4}$in. or $\frac{3}{8}$in. thick to fit on top of the wood pattern; tack and glue this top on, making a neat joint. This allows plenty of metal to come and go on when finishing. Next cut the pattern in two, using a fine saw and cutting longitudinally; fit four small wire dowels to enable you to fit the two halves together accurately; and glue a strip of cardboard to the sawn edges to make up for the material removed by the saw. Next turn two bosses as nearly as possible the same size as the gudgeon pin bosses in the old piston; these are fixed by means of glue or seccotine and a small nail each to the inside of each half of the pattern, taking great care to have them diametrically opposite each other and also exactly the same distance from the underside of the head as the bosses in the old piston. A strengthening web may be glued to the underside of the piston head if considered necessary. This web usually rises from the gudgeon pin bosses, and ascends the walls of the piston and crosses the head. If a boss about $1\frac{1}{2}$in. long and $\frac{3}{4}$in. in diameter be left on the outside of the piston head (and, of course, in the centre) it will greatly facilitate turning.

I will not go into the question of turning up and fitting the piston, as that would take up too much time and space, and it is supposed that the reader is a sufficiently skilled mechanic to do that part of the work without instructions. I have described the making of the pattern because so few amateurs have any idea of pattern-making, though they may be very excellent workers at both lathe and bench. With regard to piston rings the following is about the best method.

Turning the Rings.

If it is intended to turn eccentric rings, turn the outside to the required size first, then knock slightly off truth and turn the inside to the required size, the object being to prevent fracture of the rings when cutting off, which might easily occur if the parting tool were to cut through one side before the other. With regard to the diameter of the rings, turn them the same as, or slightly larger in diameter than, the old rings in their expanded condition. After cutting off and before making the step-cut see that each ring is a nice fit for the groove it is intended to fit, and always fit each ring to its own particular groove.

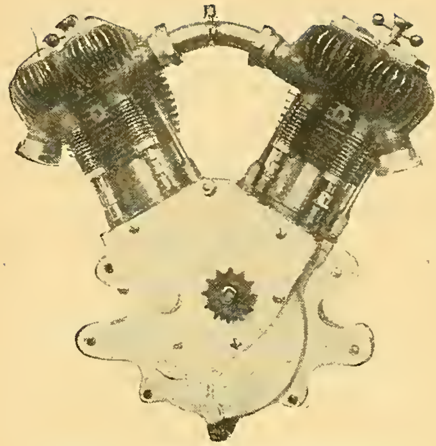
The best way to step-cut the rings is, with a small square file, to cut half-way through the ring at its thinnest part, turn the ring, and cut half way through or until the corners of the two cuts meet.

Now take as a mandrel any old thing about 1in. in diameter; turn up one end, reducing it to, say, $\frac{3}{4}$in. or $\frac{5}{8}$in., leaving a nice square collar, thread the reduced end to within $\frac{3}{4}$in. or 1in. of the collar, and fit a nut to the threaded portion. Next on this mandrel turn up two discs of any convenient thickness—$\frac{1}{4}$in. or $\frac{3}{8}$in. will do—to such a diameter that they will easily slip into the newly-bored cylinder. Place one of the rings between these discs, close the ring, and clamp it between the discs by means of the nut on the mandrel, taking care, of course, that the ring is as accurately centred as possible. Now with a round-nosed tool carefully turn down the ring until it just fits the cylinder, finishing with a fine file or with emery-cloth. By using a sharp tool and taking a light cut there is no danger of breaking the ring. If "R.D." makes his rings by this method he will obtain good compression immediately, and his cylinder will not be damaged in the "running-in" process. A little thought will demonstrate the folly of grinding in rings by using emery or carborundum in the cylinder, because it is obvious that by this method the cylinder is ground just as far off truth as the rings are ground to truth, and unless the rings are kept in the same relative position to the cylinder (circumferentially, of course, not longitudinally) good compression cannot be obtained. I hope these few tips will be useful.

H.H.

The New 7-9 h.p. Twin-cylinder Blackburne Engine.

Bore and Stroke 85 mm. × 88 mm. = 998 c.c.



The bore and stroke of the engine are 85 mm. × 88 mm. = 998 c.c.

THE firm of Messrs. Burney and Blackburne, Tongham, Surrey, is one which was founded by young and enthusiastic riders, who certainly knew what was best in motor cycle design. At the outbreak of war every one of the principals of the firm—the brothers Burney and the brothers Roberts—answered the country's call, and one, alas! sacrificed his life. Since those days the company has undergone one or two changes, is now under new management, and has extended to a considerable degree. The services, however, of Mr. J. S. Holroyd are still retained. He is the company's designer, and is well known to our readers as a competition rider of conspicuous pluck, who has had a lengthy experience on the road.

Interchangeability.

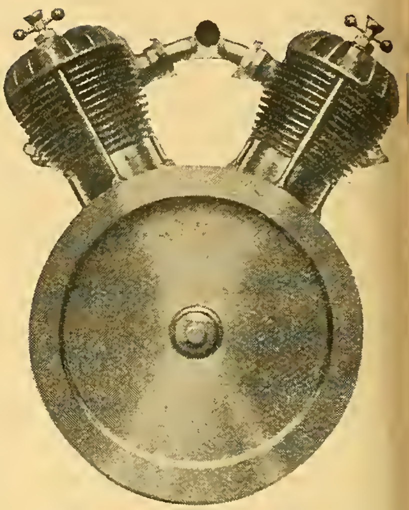
In designing the 7-9 h.p. Blackburne Mr. Holroyd has borne in mind the successful 3½ h.p., that well-known single-cylinder, the extreme reliability and sweet running of which rendered it so successful in many competitions prior to the war. Practically every part of the twin is interchangeable with the 3½ h.p. single, which, of course, simplifies the spare part question to a great extent. The cylinder dimensions are the same, viz., 85 mm. × 88 mm., and the cubical capacity of the twin is 998 cubic centimetres.

The photographs of the engine will show that the cylinders are identical except for the slight variation in the design of the combustion head necessary in the case of a twin-cylinder engine, and this combustion head retains one of the earliest forms of exhaust valve caps provided with a means of radiating heat. The cylinders are held in position by three bolts, which are screwed into the aluminium of the crank case, and it is interesting to note that the threads of these are tinned before being inserted, the theory being that two white metals will grip better than plain steel against aluminium.

A portion of the engine which is different from the 3½ h.p. is the crankshaft, which we illustrate without the balance weights, these being attached later. The right-hand portion of the crank cheek and crank pin are now machined from one piece, and are hardened and ground, but the left-hand portion is secured by a key, a taper, and a nut, the latter being finally made fast by means of a grub screw. The object of this is to enable the forked connecting rod to be easily fitted. The design is certainly good, and should be effective. On the opposite side of the right-hand crank cheek, not shown in the illustration, is a small hole, from which a groove runs for conveying oil to the hollow crank pin, which is drilled in the centre, so that, as the crank revolves, oil is picked up by the grooves and forced out through a hole in the centre of the crank pin, thus adequately lubricating the big end bearings.

Engine Details.

The crankshaft runs on Skefko self-aligning ball bearings, each having a double row of balls, which are pressed into the crank case. The same piston as fitted to the 3½ h.p. is employed, and is provided with a hollow gudgeon pin, which is secured by a set screw, the end of which passes through the boss into the centre of the hollow gudgeon, and is then fastened with a split pin, while, as a further means of anchorage, the lower of the two step-cut rings with which the piston is provided passes over recesses cut at each end of the gudgeon pin.



Flywheel side of the Blackburne engine.

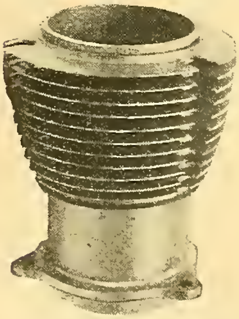
The Magneto Drive.

As an illustration of how interchangeability has been carried out in the design of this engine, we may mention that the exhaust union nut is identical with the two union nuts at each end of the inlet pipe, while, further, the two larger timing pinions are absolutely interchangeable, so that if the timing cover be changed for another which is suitable the magneto driving sprocket can be carried on the other side, so that with the least possible amount of trouble the magneto may be fixed to either side of the engine, or, if necessary, a bevel gear can be supplied which will enable the magneto to be fitted to a bracket in front of the timing gear case as in the engines on the latest Morgans. The timing gear is simple and well designed.

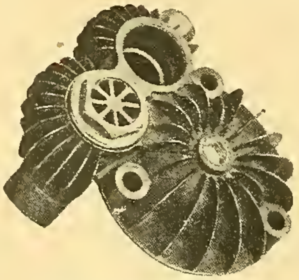
If desired the engine can be fitted with water-cooled cylinders.

Of course, the outside flywheel, so long a feature of the Blackburne, has been retained, and that fitted to the 7-9 h.p. twin weighs 20 lb. This engine will fit any frame suitable for a J.A.P. engine without there being any need to alter the belt or chain line.

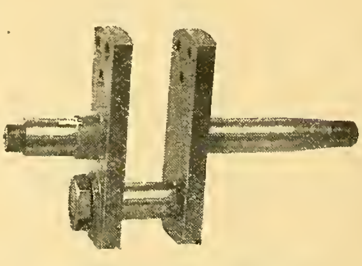
Altogether, we were much impressed by the excellent finish, workmanship, and simplicity of design of the latest Blackburne production.



The cylinders are held in position by three bolts screwed into the aluminium of the crank case.



Combustion head. Note valve caps designed to radiate heat effectively



The crankshaft runs on Skefko self-aligning ball bearings

The lower of the two step cut piston rings passes over recesses cut on each end of the gudgeon pin.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

PETROL FOR SOLDIERS.

Sir,—Referring to the granting of petrol permits to men of His Majesty's Forces while on leave or convalescent, it might interest some of your readers to know that there is no chance of getting a permit unless the applicant can show that the motor cycle is registered in his own name.

For instance, my brother and I have been using one machine between us for two or three years now, but during my leave I could not get a permit, as it was registered in my brother's name. Therefore, if brothers (or others) are joint owners of a machine, they will have to keep transferring the registration from one to the other before commencing their leave, or the permit will not be forthcoming. JOHN V. H. TURNER, A.B.

Sir,—My son came home on leave from France on November 24th; the day after he wrote to the Petrol Control Board for leave to ride my 6 h.p. Enfield and sidecar with myself as passenger. He enlisted at the age of sixteen years and two months on August 26th, 1914, and has gone through a great deal of fighting since. All that he requested from the Control Board was leave to use some petrol I had saved for him. On the 30th he saw in *The Motor Cycle* that the Petrol Board would allow leave men to get petrol for any purpose. Acting on this we went for a ride to Windermere to see some friends, and came back last Wednesday without any interference from the police. My son returned to France on the 7th inst. On Saturday morning a letter came from the Control Board to say that they could not allow him to use the petrol for the use he wanted. I understand that the Control Board are prepared to grant licences to buy petrol to men on leave, but in this case they refuse leave to use the petrol we had; also, what is the use of granting leave to ride and not replying till the men have gone back? I may say that he informed them of the date he had to return. Thanks to the announcement in your paper, we got all the riding we wanted. H. BROGDEN.

AUTOMATIC LUBRICATION.

Sir,—I have read with great interest the articles you have published from time to time in the "Blue 'Un" concerning lubrication. Having now run my T.T. Norton, fitted with a Best and Lloyd throttle-controlled mechanical lubricator, about 5,000 miles, I can safely say that lubrication worries have entirely disappeared. I use the machine daily in any and every weather condition, and have even put the sidecar on, thus pulling more than double load, so that the engine has been called upon to do more than it was really designed for. As you no doubt are aware, by overloading weaknesses are made known. The great feature is, of course, really economical lubrication. I have got all adjustments down as fine as I can at present get them, and my last quart of oil ran me 994 miles, and the quart previously 987 miles. "Coolie" and Price's Huile de Luxe respectively were used. Even at these figures the engine is over-lubricated. Mind you, none leaks out, as I exercised great care in fitting bearings and joints. Personally, I do not think 5,000 miles per gallon is at all impossible. I have to decarbonise at 600 miles. I do not try to run longer than that. No appreciable difference is noticeable with summer grade and winter grade oils so far as consumption is concerned, which, I think, is solely due to the automatic ball valves used. I fitted the sight feed in the usual position on the tank, and at various throttle openings and engine speeds the flow of oil is distinctly seen; just a glance when in doubt—not *give a pumpful to make sure.*

Just one more item. The petrol consumption has been 113.4 m.p.g.—quite a passable all-round consumption. If there are others who have got better m.p.g., then it is to the benefit of the industry to make it known, although the times are not as they might be for competition purposes in this respect. SNOSTONE.

Surrey.

A ONE-LEVER CARBURETTER.

Sir,—The logical development of every machine and system being in the direction of simplification—not necessarily mechanical simplification, but operative simplification—it is rather surprising that a more insistent demand has not been evidenced for some attempt at a reduction in the number of "twiddly-bits" on the present-day motor bicycle, which really strike one as being quite formidable after the simple easiness of driving a car. Mechanical lubrication for motor cycles appears to be on the way now, but it seems to me that the carburetter controls even more urgently need attention. Looked at in the hard white light of criticism, the two-lever carburetter, it must be admitted, is only a halfway stage in the evolution of the ideal.

It would be of considerable interest, I think, if some of your readers, both technical and lay, would give us the benefit of their experience of the single-lever carburetter as regards freedom from mechanical trouble, satisfactory carburation at starting and at speed, and economy in consumption. LEWIS DICKINS.

PISTON-RING FRICTION.

Sir,—Permit me to remark regarding "Chinook's" blast of hot air in January 17th issue of *The Motor Cycle* that he seems to have designed his deep piston ring when enjoying an after-dinner cigar. It is quite impracticable. Suppose the piston to be 3in. in diameter, the ring—$\frac{5}{16}$in. deep—would require to be opened out to at least a 2in. gap to slip over the top of the piston. The depth of the ring must be limited to much less if it is to be successfully sprung into position. W. M. BROWN.

Sir,—"Chinook's" article calls for comment. Is not 1,000 r.p.m. a high figure to give as the average difference between engine speed of a high-efficiency engine (so-called) and the more orthodox type? Considering it is current American motor cycle practice to fit three piston rings, is not "Chinook's" statement on that particular point extremely absurd? Will "Chinook" give his authority for stating that "the leakage of gas between the rings and cylinder is infinitesimal compared with the leakage round the back of the rings," and has "been proved by *practical research*"?

Is the friction of the rings due more to their face contact with the oil film, or to the scraper action of the sharp edges of the rings piling up oil in front of each advancing ring's edge? I am inclined to think the latter is the fact, and therefore cannot see where the utility of such a ring as suggested by "Chinook" comes in.

It would be very interesting to have the opinion of your two-stroke rider readers on "Chinook's" theory that the gumming up of piston rings in their favourite mount is due to escaping hot gas. With visions of the nervous strain, usually engendered when removing and replacing piston rings of the ordinary type, I should feel compelled to specify on any engine of mine that rings of "Chinook's" type should *not* be fitted (if they ever come to the stage of being subject to such rejection, which I very much doubt). J.W.

Belfast.

PETROL FOR MUNITION WORKERS.

Sir,—I was particularly interested in your remarks in your issue of January 3rd regarding a small allowance of petrol to motor cyclists who are engaged on important war work. Those of us who are engaged every day (including Sunday), with day and night shifts, absolutely all out on the manufacture of munitions, feel that if it is at all possible to spare a small quantity of petrol or substitute for an occasional recreative run something should be done to help us.

I would not suggest more forms to be filled up, or any additional clerical work for the Petrol Control Department—simply a statement on our present licence that not more than two gallons per month be used for recreative purposes, and trust to our honesty. For myself, during the past two and a half years my motor cycling has been confined to occasional runs on Saturday afternoons or Sunday nights out into the country for a breath of fresh air, with peace and quietness. Even as recreative runs the petrol was not entirely wasted, for it was while away from the noise and hurry that I got most of my ideas for methods and machines which are holding records in the quick production of munitions.

We feel that the present restrictions are more due to newspaper campaign than actual necessity, else why allow so much petrol and oil to be used by motor vans every Sunday delivering Sunday newspapers?

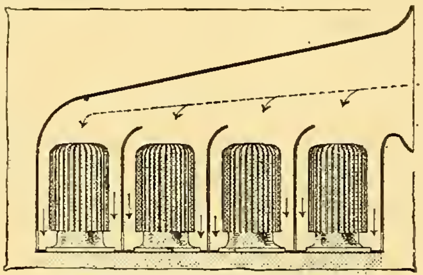
Recently I examined a number of these papers, and found only a very small space devoted to the previous night's war news, the rest of the paper being made up of breach of promise cases, divorce actions, murders of individuals, and reviews upon the war, football, advertisements, dog-racing, and photographs of nothing in particular.

To an engineer, there appears to be nothing of national importance making it necessary to have these papers specially distributed by motor vans.

We base our claims that if it is possible to allow so much petrol to be used for the above, some consideration ought to be given to those who are giving their level best to further the output of war material in particular.

Glasgow. WORKS MANAGER.

COOLING AERO ENGINES.



A suggestion for cooling aero engines.

Sir,—*Re* cooling problems on aero engines, published in *The Motor Cycle*, would it not be possible to enclose cylinders as sketch, and direct the cooling draught down and all round, so that the hottest part of the engine would get the cold air direct instead of on one side only?

F. WHITWORTH.

GOODS MADE IN GERMANY!

Sir,—It is impossible for me to allow F. Jones's letter in *The Motor Cycle* of January 3rd to pass without some comment. Judging by the composition, it seems to be the work of a six-year-old schoolboy, and by the grammatical mistakes it gives the impression of a foreigner (perhaps a Hun) able to put a few sentences together. Now, F. Jones wants the proprietors of *The Motor Cycle* to do as he says, and unless they do he and his very few friends will ask the "Blue 'Un" to retreat from his immortal library. Let me tell F. Jones that if he and his few friends abandoned the "Blue 'Un" it would make no difference to the proprietors, but if he managed their affairs it would make the world of difference to the company.

In my opinion, as an old reader, he is simply a scaliwag and unworthy of anything British. BRITON.

Grovesend, Glam.

Sir,—I wish to congratulate you on the very excellent articles you have lately published on the chemistry and physics of internal combustion engines. They are first-class. Also on your stand against "Goods made in Germany": the type of mind that calls such a genuine effort to carry into effect the freeing of our nation from German domination "Political propaganda" is one which need never be feared by "sportsmen." It would be interesting to know whether your correspondent belongs to the "No Conscription Fellowship" and other kindred bodies. We all, however, respect him for signing his name. F. C. LEES.

Sir,—Mr. T. Tanner uses the arguments of the professional pacifist, though in view of his assurance that he is a discharged soldier of September, 1914, I can only assume he uses these arguments without careful deliberation.

He sees further war if we boycott German goods, but he appears to forget that previous to this war German goods were allowed in this country without taxation or penalty. German manufacturers had the privilege of exploiting this market without paying their share of taxation as does the English manufacturer, and, in spite of this, Germany bolted and barred its doors against our manufactures, unless we were prepared to pay the penalty of protective tariffs.

With regard to the profiteer, Mr. Tanner is surely not so simple as to think that the opening of our markets to the Boche will eliminate the profiteer. Opportunities create profiteers, and when our Allies and our own manufacturers are able to compete, and are free from war orders, the profiteer must disappear.

Mr. Tanner's conception of the brotherly spirit is, in my opinion, a selfish conception altogether, as he states that he is going to buy the German article if it suits him best. Surely with the violation of all national law, and the sinking of our hospital ships so fresh in our memory, we are not so weak as to encourage amongst us such a treacherous, unmanly, and ungenerous neighbour.

The president of the Institution of Electrical Engineers wisely stated in his inaugural address that the German salesman has to learn that his wares, like his deeds, stink in our nostrils, and that no Briton who values his self-respect can enter into any sort of intercourse with members of a nation that bedded our wounded men, prisoners in their hands, on horse-dung, and kicked and spat upon them as they lay in silent agony. M. H. GOLDSTONE.

Sir,—I am afraid I cannot refrain from two or three remarks on the above subject. When the notice was first published it struck me as being quite a worthy and patriotic idea. But, on consideration, I am inclined to think that Mr. Ives is right in censuring it. Surely the latest suggestions *re* peace terms include a clause to the following effect: "There shall be no trade war."

The enormous populations of Germany and Austria must live somehow after the war; and they are not, and cannot be entirely, independent of the products of other countries. They must go somewhere in order to obtain these products, and therefore they must reopen trade with other countries. Are the supporters of your notice prepared to stop the sales of British goods to Germany? If not, and they expect these to be resumed after the war, how do they expect them to be paid for unless we buy goods from Germany? X.Y.Z.

Highgate.

Sir,—Referring to the letter of Mr. Chas. S. Ives under the above heading, in your issue of December 13th, I fancy if he boycotts all papers that preach a propaganda with which he does not agree, he will go paperless to bed. Further, if I may be allowed to say so, I think it is a great mistake to confine oneself to papers which preach one's own ideas; it leads to political narrow-mindedness—a very undesirable position.

I thoroughly agree with you, Mr. Editor, in your boycott of "Goods made in Germany," and think the great majority of your readers would say ditto. Personally, if, in the future, I cannot get a motor cycle without German parts, I will stick to my push bicycle. To do otherwise would be a funny way of showing our gratitude for the great sacrifices that have been made by our fellow motor cyclists in the great war. G. WILLIAMS.

Sir,—Can you spare me an inch of space to reply to Mr. Maurice Little (a most appropriate surname, exactly describing his mental outlook)? I wonder what German-made article Mr. Little is interested in. He talks of a clean, sporting journal. Why? I fail to see how the element of sport enters into the question; and, anyway, who wants to be sporting with a people who have not an idea of the meaning f the word? If Mr. Little saw a hefty brute about to murder is mother, would he be sporting, like a little gentleman, and ay, "Look out, put up your hands, I am going to hit you"? r would he do as I and, I think, most people would do— ackle the murderer from behind with a knuckle-duster, failng a more deadly weapon, or else kick him well?

As a matter of fact I do not believe he would do either; e would probably run away, if I am any judge of character.

I daresay Mr. Little, the Pacifists, and other pro-Germans, vould like to see an economic peace with Germany after the var, but I do not think anyone else would.

In conclusion, you are quite at liberty to furnish your correpondent with my address if he desires it. And if he takes xception to anything I have said I shall be most happy to neet him and discuss (!) the matter; but I give him due varning that I shall have an armed friend near to be on the ook out for his German "sporting" tactics.

E. J. L. STRONG.

DEAL MACHINES.

Sir,—I read with interest Hurtebize's article on "Ideal Machines" in the issue of December 13th, and I note that he is sighing for a flexible motor bicycle. He stipulates silence, flexibility, power—not extreme speed—and comfort; also two speeds only, steady engine, and one that approximates to the old 2¾ h.p. De Dion.

Now there is one machine that fulfils all these conditions, and that is the 3½ h.p. two-speed P. and M. I have ridden four machines of this make of years ranging from 1906 to 1913, and the same qualities have been distinguishable n each.

The P and M. is a low compression engine like the De Dion, and I think this accounts for its flexibility. It s also the easiest starter of any machine I have ridden. I agree it would be improved by rear springing, but this seems to be the only point in which it differs from your contributor's ideal machine.

I may say I have no interest in the makers, but am a great admirer of their product. FLEXIBILITY.

Leeds

CENTRIFUGAL FORCE.

Sir,—"G.R.B." asked "Mohandis" to adjudicate between he former and me.

"Mohandis" has given judgment against me, when he ays I was confused between "the mental and muscular operations which control the forces that hold a bicycle upright and the forces themselves."

Then he declines to sum up the pros and cons of the discussion, so I venture to undertake this task myself.

I was not wrong or confused, as stated in above quotation. For let "Mohandis" ask a despatch rider after a long ride: Are his muscles aching? If they are, what made them ache? Holding up the bicycle? "Mohandis" admits the mind plays an important part in riding a cycle, but he adds t is only a controlling operation, which I take to imply that he mind is not a force. This may be correct, but he includes he muscles, and where the mind, the nerves, and muscles each begin and end I do not know.

It may even be that it is the same force which operates the mind that moves a motor cycle, or an electric train, or a team engine. George Stephenson explained the force of the ocomotive as "bottled up sunshine." Maybe all force comes rom the sun, and is the same. However, we have arrived at the conclusion that the forces holding up a ridden cycle are: A. Centrifugal force. B. Gyroscopic action of the wheels, etc. C. Altering the base of support under the centre of gravity. D. Physical (mental ?) force of the rider.

A and B are in evidence when the cycle is moving, and ncrease in ratio to the speed. They are not present when he cycle is stationary.

C and D are always present, but are most in evidence when tationary or travelling slowly, and are *the* forces which upold a cycle and rider. They are assisted by their servants A and B. Then again, when A and B are most in evidence viz., at speed), C and D must still be the dominant forces, or disaster will occur; and, should the machine travel so quickly that A and B become the stronger forces, there will happen "speedman's wobble."

When cornering at speed a rider will use his weight to ssist his muscles to master A and B, which, in my opinion, ombined with the numberless corrections to A and B which have become necessary by unevenness in the road, etc., is quite enough to cause muscles to ache.

I beg to thank "G.R.B." and "Mohandis" for their interesting contributions, and ask their forgiveness for the following: "I think they are engineers, and as such they overlook the rider. They talk about the cycle doing this, that, and the other. Their minds are mostly on the engine and machine; but a motor cycle is incomplete without a rider, and it is more under the influence of mind, muscle, and nerve than any other machine of which I can think—except a mangle." TOP HEAVY.

Newcastle-on-Tyne.

EXPERIMENTAL AERO ENGINES.

Sir,—Your able contributor "Ixion" has honoured my letter on the subject of State aid for inventions with a lengthy and somewhat ambiguous "Comment," and as "Ixion" evidently did not read, or at least inwardly digest, the subject matter of my letter before starting out with his journalistic bludgeon, may I point out to him that I did not mention, let alone criticise, the Royal Flying Corps, but dealt merely with what appeared to me to be an exaggerated statement on the possibilities of State aid for "promising aero engines."

"Ixion" declares his opinions of "inventors" with all the fervour our religious forbears used towards "heretics," and, while disclaiming all personal knowledge, uses my name so freely, and claims sufficient acquaintance with my designs and experience to assert his own superior knowledge, that I am open to "bet a gallon of No. 1" to a "spot" that he is one of the official disqualifiers.

As "Ixion" appears to be still enthralled with the bogey of "Deutschland Uber Allies," may I remind him that Germany certainly did take precedence over all nations in supplying State aid, and regarding her policy with aero engines, refer him to the masterly summary of that policy in the issue of January 17th.

The subject of "making good" has nothing to do with the case, and a large number of so-called "scientific" reputations are based merely on the ability of the individual to expose the knowledge he has accumulated in a fluent manner, while another individual applies similar knowledge to a practical purpose and is dubbed a mere engineer.

"Ixion" endeavours to cover the official apathy under the veil of standardised production, but during the first year of the war there were no settled designs to be reproduced! May I ask "Ixion" why he has not made up his mind and produced a standard motor cycle; also, why did the Americans find it necessary to design an engine when the truly marvellous engines developed by the Allies were at their disposal, if it was not to secure that last "ounce of efficiency"?

In conclusion, I should like to thank "Ixion" for the semi-official confirmation of the warning conveyed in my letter, and to suggest he should devote a few "Comments" to the improvements that are considered essential in official circles.

Glasgow. M. E PHILBROW.

3D.

THE PRICE of THE MOTOR CYCLE

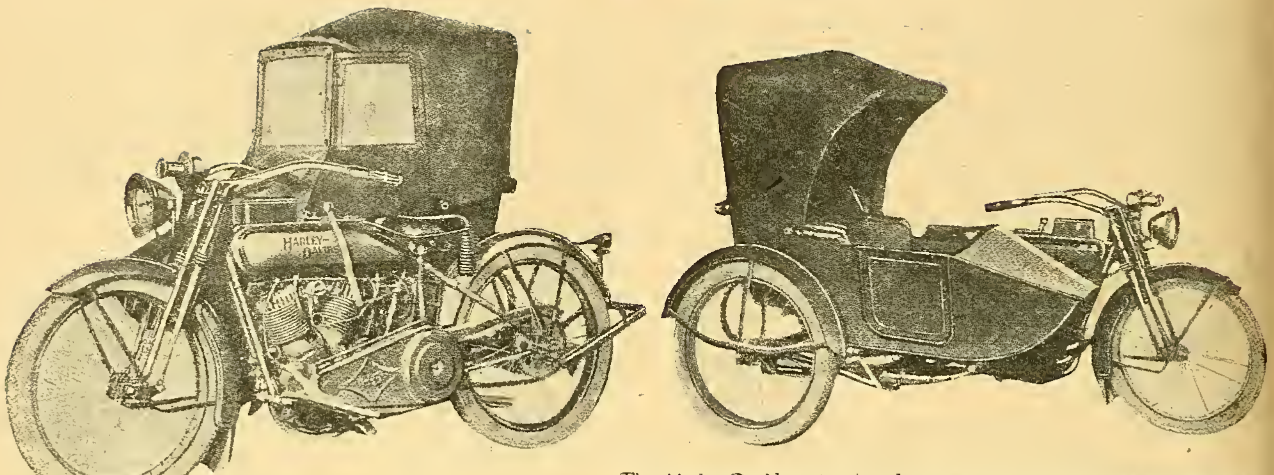
TO BE RAISED TO 3D ON FEB. 7th.

This further increase is necessary owing to the drastic restriction imposed on the import of paper and paper making materials during 1918 and the consequent heavy advance in the cost of paper, but the price will be reduced as soon as circumstances permit.

The subscription rates will be correspondingly raised on renewal or to new subscribers:

British Isles	15/2	per annum, post free.
All countries abroad..	19/6	" "

All subscriptions current at the time of reducing the price will be proportionately lengthened for the benefit of each subscriber.



The Harley-Davidson hood and screen recently placed on the American market. A feature worthy of note, although not a new idea, is the wind deflector, which is part of the screen itself, and protects the passenger from air currents thrown off from the rider's body when travelling.

The Need for Petrol Economy.

THE *Daily Mail* for January 25th publishes some remarks of Mr. A. Shrapnell-Smith, Economy Officer to Mr. Walter Long's Petroleum Executive Committee. Mr. Shrapnell-Smith's duty consists in seeing that waste of petrol is checked in all spheres, and his remarks on the continued need for rigid economy in the use of petrol are interesting, and we think they will be considered as a serious warning as to the unsatisfactory nature of the present fuel situation. "Visible stocks are no test," says Mr. Shrapnell-Smith. "The only real test is the supply landed each month. This test now, compared with six months ago, shows a very marked decline. There is a direct connection between petrol economy and the price and supply of food. A gallon of petrol in a commercial lorry moves three tons of food eight miles. It is not much use having food in the country if it cannot be distributed."

Mr. Shrapnell-Smith also states that coal gas is being used, where possible, for army transport, or for driving any internal combustion engines where practicable. He concludes his remarks by saying that paraffin is not rationed because it is the light and fuel of so many thousands of poor people, but it may be shortly.

There is no doubt that there is still a feeling that there is plenty of petrol about, but Mr. Shrapnell-Smith is particularly careful to point out that a real shortage does exist, and not only does exist, but may get worse. There is, indeed, a rumour abroad that in a few months time petrol will cease to be issued for civilian purposes.

* * *

Home-produced Fuel.

"THE following statement," says the *Board of Trade Journal* for January 17th, "has been issued by the Ministry of Munitions respecting the policy of the Ministry on the production of oil from home sources:

"Certain communications have recently been made to the press upon the subject of the production of mineral oil from home sources. These communications are apparently based on incomplete information, and therefore may have created a mistaken impression.

"Apart from the very serious technical difficulties which have to be overcome, the competing claims of other urgent war services for labour and materials render impossible the rapid development of methods which might otherwise be pursued with advantage. The Ministry of Munitions, however, has been steadily pursuing the policy which is considered to be best designed to produce substantial results in the shortest time. It is obviously undesirable to explain the actual methods or to state the quantities of oil which it is estimated will be produced, but it is thought that some indication may be given of the general policy which is being followed.

"All existing plant at the shale works of Scotland and the gasworks and coke ovens throughout the country are being pressed to their full capacity and are being extended as far as present circumstances permit.

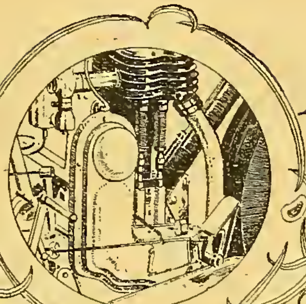
"It has been found by experiments that certain plants already in existence can be adapted in a short time to treat new material by new methods. This adaptation of plants is being actively pursued, and has the obvious advantage of saving labour, time and material, and making the best use of existing staff and equipment. On the other hand, where suitable raw material cannot be dealt with on existing plants, arrangements are in progress for erecting works for the extraction of oil.

"Some of the correspondents suggest that a very large output of fuel oil can be obtained because one unit can produce or has produced a given quantity of oil. In the present state of supply of labour and materials any such easy multiplication is liable to be entirely fallacious." Nevertheless, the statement is very interesting.

A CLEAN REPAIR.

The accompanying illustrations show a pair of Scott motor cycle cylinders badly cracked by frost. As will be seen, practically the whole side of the cylinder on the left was bulged out by the pressure. The same cylinders are shown after a clean weld by Barimar experts leaving no trace either of the fracture or the weld

QUESTIONS AND REPLIES



Loose Ball Bearings.

The ball race cages of my 5-6 h.p. Rudge-Multi will revolve in their housings. Is it advisable to have them fixed? If so, can you suggest the best way of doing this?—A.H.B.

Yes, it is advisable that the ball bearings should be fixed in their housings. Perhaps the simplest method would be to wedge them with a thin strip of brass, placed round the cage.

Loss of Compression.

I have recently overhauled my 1914 Triumph motor cycle. I carefully removed all the carbon deposit from the cylinder and piston and ground in the valves. I carefully replaced the cylinder and valves, but when I took it out for a trial run I fancied that the compression was not so good as it had been previous to cleaning. I may state that when I removed the piston ring and cleaned the groove I found that the ring, when replaced, was fitting very loosely. Would that cause less compression? Also, I find that air is sucked in and discharged through the axle of the pulley. There is no play in any portion of the engine.—BO 1195.

It is by no means uncommon to find, after you have removed the carbon deposit from a motor cycle, that there is not so much compression and that the engine does not pull so well for the first 100 miles or so. This is due to having removed the carbon from round the piston rings, which it is not always advisable to do unless the rings are stuck; also to leakages round the valve caps, etc., which finally make up with burnt oil. The air sucked in and discharged through the hole in the centre of the main axle is the natural state of affairs, crank case compression release taking place in this manner.

Storing a Motor Cycle.

I intend to lay up my motor cycle and sidecar for several months. I should be greatly obliged if you would tell me the best way (1) to prevent the tyres deteriorating, and (2) to lay up the engine. I have already removed the tyres and enamelled the wheels, removed all the driving chains and put them into a bath of lubricating oil. From a cursory glance at the Enfield gears, I conclude that vaseline would impair the efficiency of the bands. Is this correct?—C.H.R.

(1.) The tyres should be hung up in a dark, cool place, while the tubes may be stored in a box full of French chalk.

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

(2.) The best plan is to take the engine completely to bits and wrap up every part, after thoroughly greasing it, in oily cloths. If the machine is to be stored in a really dry place you need not go to this trouble. First, liberally over-oil the engine, and run it till it very freely exudes dense smoke from the exhaust. Before it cools, apply thick cylinder oil to the outside of the cylinders with a paint brush. The oil will run freely into all the nooks and corners if applied while the cylinders are still hot, while the over-oiling will have assured the whole of the engine—including valve mechanism and the combustion heads—receiving a thorough coating of oil. When finally the engine is left, see that all valves are closed. Vaseline should not impair the gripping efficiency of the expanding rings of the Enfield gear. If it were found to do so, it would be a simple matter to wash out the vaseline with petrol or paraffin and refill the gear with oil.

Use of Coal Gas.

With regard to the recent Petrol and Gas Order, I take it that gas may not now be used for pleasure rides. Is this so? Also, would it be legal to make a gas trailer myself for my own use? I have the necessary wheels, and could easily make the axle, springs, and other fittings. Would it be necessary to carry a rear light on the motor cycle as well as on the trailer?—W.C.

The Order relating to the restricted use of coal gas comes into operation on February 9th, before which date you may use gas for any purpose you think fit. After this it may only be used under the same conditions as petrol. There is nothing to prevent your making a gas trailer, but do not do so until after you have communicated with the Petrol Controller's Department of the Board of Trade, 19, Berkeley Street, London, W.1, regarding a permit. You need to carry a rear light only on the rearmost vehicle, *i.e.*, on the trailer.

Tuning an F.N.

Could you give me a few pointers upon the tuning up of a four-cylinder F.N. a.i.v. for speed? Would you advise timing exhaust valves to close, say, 3 mm. past the top, and also original springs in inlet with 1/32in. opening, or stronger springs, and, say, 1/16in., or even 1/8in.? Would you fit stepped piston rings on top of pistons? Would a modern carburetter be an improvement on the original F.N. for speed? Would the machine tuned up and faked approach 60 m.p.h.? Would it pull a sidecar without a two-speed gear?—A.B.

We think your suggested timing for the F.N. should give satisfactory results, while stronger inlet springs would certainly make for greater speed, but if too strong they might prejudice the ease of starting. The question of stepped or plain end piston rings is largely a matter of opinion, and we do not think there will be much gain in fitting either type over the other. The old F.N. carburetter is, of course, now somewhat out of date, and no doubt a more modern instrument would be a considerable improvement. If the machine were in first-class order and tune it is possible that you might reach 50 m.p.h., but this is a very high speed. If you had your machine tuned up so that it would give this speed it is doubtful if it would pull a sidecar with full satisfaction, as the timing for pulling and that for speed are somewhat different. However, the machine should pull a light sidecar satisfactorily in a fairly level country.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY.

During 1918 the restriction on the import of paper and paper making material is very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week

Two-stroke Hints.

(1.) I have at present my $2\frac{1}{4}$ h.p. Levis motor cycle down for overhauling and cleaning, and I am thinking of joining the local Motor Volunteers, but I have not yet sent for my local taxation licence; shall I be right if I ride my machine on duty until my licence comes? (2.) Is it advisable to put any oil in the crank case when I re-assemble my machine, and what sort of oil is best? (3.) Do you think I shall get better mileage from present-day petrol if a hot air intake be fitted, and what is the best sort of intake to fit?—A Loyal Reader.

(1.) We should not recommend you to ride the machine until you have all the requisite licences in your possession. (2.) Put about three pumpfuls of air-cooled oil in the crank case of your engine. This cannot do any harm. Any good oil for air-cooled motors will do. (3.) Certainly a hot air intake would improve the consumption and running of the engine. The hot air intake should take the form of a funnel, bringing the warm air from the radiating fins, preferably at the back of the cylinder, into either of the air inlets of the carburetter.

Fitting a New Piston.

Having had the misfortune to irreparably crack the piston of my $3\frac{1}{2}$ h.p. engine, the only pattern piston I can get is $5\frac{1}{2}$ oz. heavier and $\frac{1}{2}$in. shorter in the skirt than the original, but the distance between the top and the gudgeon pin hole is the same. (1.) Will the extra weight of this piston upset the running of my engine? (2.) Is it necessary to have it lightened, and will turning the top concave lower the compression and affect the h.p. in consequence, as I do not like the idea of drilling holes in the sides of the piston unless you advise this? I might say that the suggestion of turning the top concave was given me by the firm supplying it, as the top has ample thickness to allow this to be done. (3.) Will the shortness of the piston be any disadvantage, as half an inch seems rather much? (4.) What sort of fit should a piston be in the cylinder without rings, and do you think this too slack?—that is, when cylinder is laid on its side with the piston in flush, at the bottom I could just get a five-thousandth of an inch feeler in between cylinder and piston at highest point. Should the piston be a friction fit, or do you think this about right?—L.J.H.

(1.) Yes, the extra weight may upset the balance of the engine. (2.) You can easily lighten the piston, not by turning the top concave, which would be distinctly inadvisable and would lower the compression, but by getting the piston turned out inside beyond the bosses through which the gudgeon pin runs, and also round the skirt. There is also no objection to drilling boles round the skirt should this be found to be necessary. (3.) The shortness of the piston within reason should not be a disadvantage. (4.) The piston should not be a friction fit, and the clearance you have appears to be correct. The piston rings should be a snug fit with the joints just closed.

A Leaky Petrol Tank.

I have taken down my tank to repair it. The tank is held on by clips on the top tube and screws. The petrol leaks past the threads of the screws. Would you please let me know how to stop this?—W.P.

You cannot very well solder the screws into the tank, but it must be at the actual sockets into which the screws go that there is a defect. Have you tried soldering all round these? One method of testing for the source of leakage which we have carried out with great success is to block up every orifice in the tank from which air can escape, then solder temporarily into the filler cap a cycle valve complete, and fit your pump on to this, give a few strokes, taking care not to get too much pressure into the tank, and then immerse the whole in water, when the leak will be rendered visible by the presence of bubbles. We may add that the work of soldering petrol tanks is exceedingly dangerous, and we would never recommend an ordinary novice to attempt it.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

Knocking on Hills.

My machine is a $3\frac{1}{2}$ h.p. single fitted with a Philipson pulley. It has a sporting canoelet sidecar, which is very light, attached to it, and is very fast on the level. But when going up a gradient, such as Putney Hill, it begins to konk and slow down considerably, and unless I lower the gear by putting my heel on the pulley it will probably stop, although the spark is retarded and the air lever shut. It seems to me that either the spring is too strong or the gear is too high, in which case please tell me how to lower the gear.—J.L. de V.F.

Either the spring in the pulley is too stiff, thus preventing the gear from responding sufficiently to the impulses of the engine, or the compression of your engine is too high for sidecar use. We would recommend you firstly to reduce the compression by fitting a thicker joint between the crank case and the cylinder, say, a cardboard joint, about $\frac{1}{32}$in. thick, well covered with seccotine. If this fails to cure the knocking, then you should communicate with the makers of the pulley, Messrs. Philipson and Sons, Holland Street Works, Astley Bridge, Bolton, who may possibly be able to supply you with a more flexible spring. The satisfactory working of a Philipson pulley is dependent upon obtaining a spring of the correct tension.

Choked Exhaust Pipe.

My two-stroke starts up well after flooding of the carburetter, but after running for about 300 yards—sometimes more, sometimes less—begins to knock and slow up, and finally knocks itself to a standstill. I decarbonised the cylinder not many weeks ago, so it cannot be carbon that causes the trouble. I have overhauled the magneto, and everything is in perfect order, a fat spark showing every time. No alteration of either timing or petrol level has any effect whatever, and the carburetter has been taken to pieces and thoroughly cleaned. Closing the air lever has no effect, neither does retarding the magneto. I have tried four different types of plug. There appears to be no air leak between the carburetter and induction pipe, and there are no gauzes in it.—H.H.

In all probability your trouble is due to the silencer or exhaust pipe being choked with deposit.

Work of National Importance.

I am doing agricultural repairs, and as I have to carry tools, etc., I am using a sidecar, as I have been allowed a free-of-duty petrol permit. (1.) Must I pay the £1 local taxation licence? (2.) Is it necessary for me to paint my name and address on the sidecar? (3.) If I have a job on which I require assistance, may I take a man with me?—J.W.F.

(1.) On no account pay the local taxation licence if you desire to obtain free-of-duty petrol, provided, of course, that your machine is a genuine sidecarrier, constructed and adapted for the purpose of transporting goods and merchandise. (2.) Of course, you must have your name and address on the outfit, but unless it fulfils the requirements of the Act you will be liable for the local taxation licence, and you will also have to remit to the Petrol Controller's Department the duty due on your free-of-duty permit. (3.) There is no objection to your taking a passenger with you, but the authorities will not accept the machine as a business vehicle if it is fitted with a touring body.

RECOMMENDED ROUTES.

Pembroke Dock to Warwick.—V.J.D.
Pembroke, Carmarthen, Llandilo, Llaudovery, Brecon, Three Cocks, Hay, Willersley, Hereford, Ledbury, Tewkesbury, Evesham, Bidford, Stratford-on-Avon, Warwick.

Salisbury to Nottingham.—R.F.D.
Salisbury, Andover, Whitchurch, Newbury, East Ilsley, Abingdon, Oxford, Banbury, Southam, Rugby, Leicester, Loughborough, Nottingham.

Bristol to Sheffield.—D.F.S.
Bristol, along the Malmesbury Road till you reach the cross road which leads from Bath to Nailsworth, thence through Nailsworth, Stroud, Cheltenham, Cleeve, Evesham, Bidford, Stratford-on-Avon, Warwick, Coventry, Hinckley, Ibstock, Cole Orton, Melbourne, Derby, Ripley, Alfreton, Chesterfield, Sheffield.

FEBRUARY 7TH, 1918.

Reconstruction.

THE problems involved in the work of reconstruction after the war may at first sight appear to be outside the province of a popular technical journal like *The Motor Cycle*, but if we examine them very closely we shall find that, in fact, they have a most intimate connection with the development of the motor cycle movement, and, therefore, are pregnant with interest and importance to our readers. We go further, and say that if these problems are to be readily solved it is essential that the views of the user shall be taken into account as well as those of the manufacturer and the worker engaged in the factory.

The technical press will render an invaluable service to British industries if it will undertake to give expression to the opinions of its readers and ensure that these be taken fully into account when the problems referred to are under consideration.

The demand for motor cycles immediately after the war will be many times greater than the supply. If British manufacturers wish to keep the industry a British one, they must consider without delay the many problems connected with quantity production: the obtaining of the necessary machinery in sufficient quantity and at an early date, the securing of adequate supplies of raw materials, the organisation of labour, the settlement of the wages question, financial facilities (with particular reference to Overseas trade), and generally such improvements in trade organisation as may be necessary for the purposes of more economical production, distribution, and marketing, which latter aspects are obviously of direct personal interest to the user.

It is refreshing to find that the Reconstruction Department of the Ministry is fully alive to the needs of the after-war situation, and that Dr. Addison is enlisting the services of some of the best men in the kingdom in order to deal with the various branches of the problem.

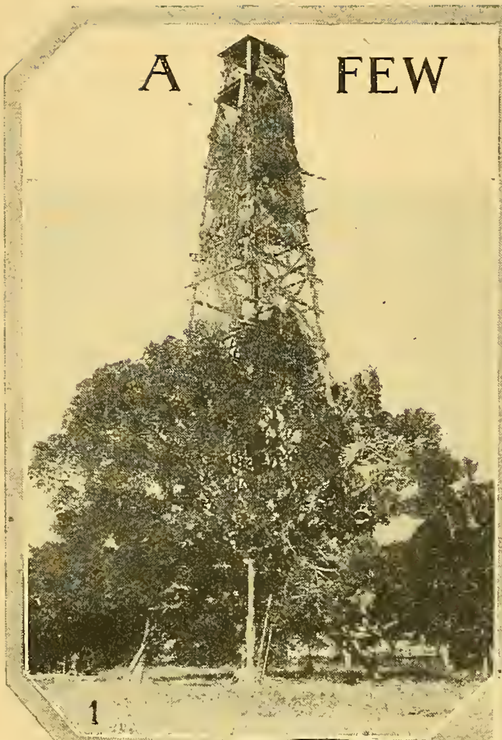
The preservation of industries in danger of extinction, the establishment of new industries, the volume and nature of the demand for British goods, and kindred matters, are all under careful consideration, and the thing of outstanding importance in that connection is that the Government intend to use the men of the industry themselves as far as possible for executive work in the regulation of trade after the war.

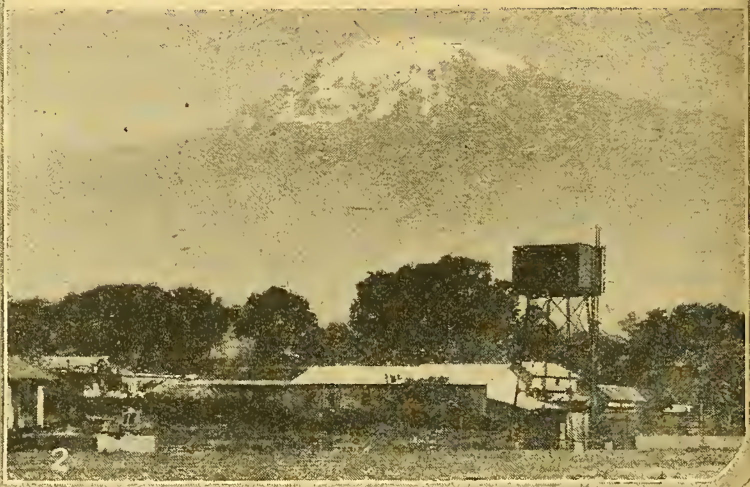
We may add that the Industrial Reconstruction Council has issued a pamphlet entitled "Trade Parliaments," which contains some very pertinent remarks upon this most important subject. In the first place, it says, almost the whole duty of the British nation after the war may be summed up in the phrase "Political and Industrial Reconstruction." Secondly, the business of reconstruction is urgent. It cannot wait. To be ready for peace we must prepare during war. Unless our schemes for industrial reconstruction are well under way when peace is declared, our industrial competitors may easily steal a march on us, and a golden opportunity be lost for ever. Thirdly, each trade has a sphere of almost incalculable importance in creating the new industry of the future.

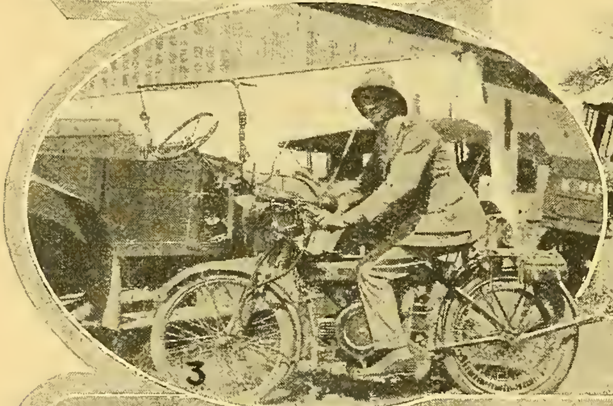
The Government can, and no doubt will, rely upon employers' associations for information on purely trade questions. But more than this will be necessary if British industries are to be developed upon the right lines. We must have the users' side of the matter adequately considered, and, if need be, protected. Labour will certainly insist upon full recognition. Why should not the motor cycle industry give a lead to other industries by the formation of a council, upon which should be represented the manufacturer, the workman, and the user? In effect, an industrial council on the lines recommended in the Whitley Report, but providing for the outside-the-factory point of view, represented by the user. Much benefit might come of it—not only for the industry, but for the movement as a whole.

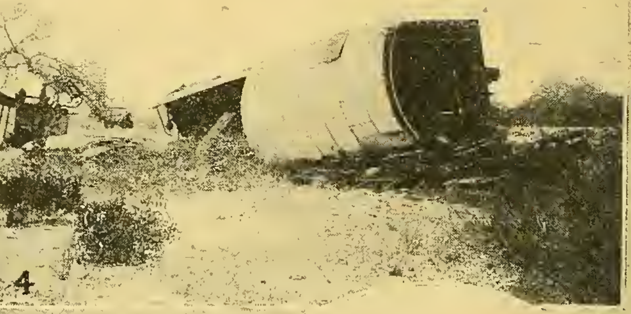
An Index to the advertisements in this issue will be found on the page facing the back cover

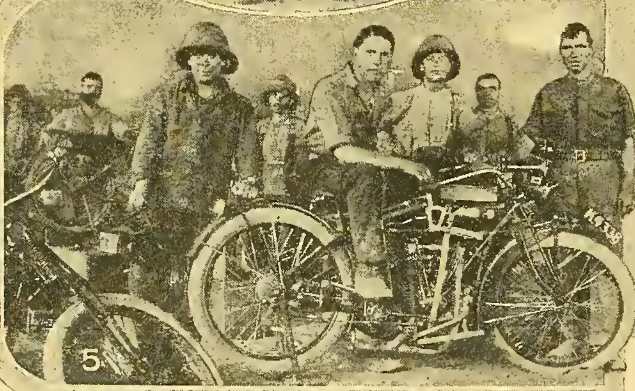
A FEW REMINISCENCES OF THE CAMPAIGN IN G.E.A.

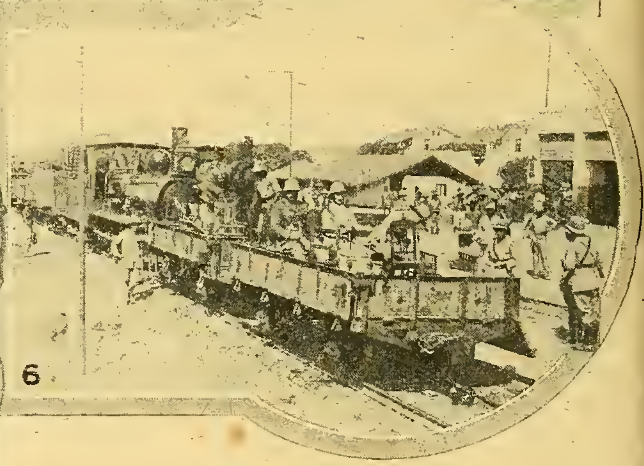












(1) A German look-out tower at Dar-es-Salaam.

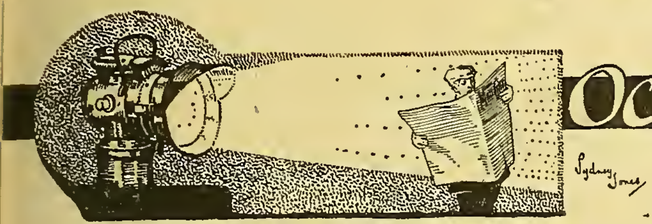
(3) J. D. Mail (Sgt. Mechanic) aboard his Douglas at M.T. Workshops, Dar-es-Salaam.

(5) A group of mechanics in a motor cycle workshop at Dar-es-Salaam. The Indian motor cycle was the first to be used on active service in G.E.A., and did excellent work.

(2) Mt. Kilimanjaro, the highest mountain in Africa. The ground in this neighbourhood is very heavy for motor cycles owing to the perpetual mud.

(4) An enemy train which was bombed by aircraft and derailed whilst in motion near Dodoma.

(6) Gen. Van de Venter on an inspection train near Dodoma.



Occasional Comments

"By Ixion"

The Tandem-seated Cycle Car.

ONE or two designers are wondering whether the public will or will not accept a tandem-seated cycle car after the war. It is evident that this design has peculiar advantages from the standpoint of wind resistance, improves the prospects of fast hill-climbing with a small engine, and thereby eases the problems of air-cooling. I was asked my opinion last week, and the hesitating designer laid great stress on the popularity of pillion riding ("flapper brackets"), and on the fact that thousands of young men have grown accustomed to tandem-seating in biplanes. The cases are not on all fours. The occupant of the flapper bracket can talk to you quite easily, as her lips are very near your ear. In an aeroplane the uproar forbids conversation, even if side by side seating were possible. There are two grave arguments against tandem seating. The first is mechanical: unless you employ wide axles the vehicle is laterally unstable, and if you fit wide axles the appearance is abominable. The second is practical: other designers will undoubtedly market good cycle cars with side-by-side seating. On the whole, I think the idea is *na poo.*

About Piston Rings.

"CHINOOK" launches us on rather an uncharted sea when he opens the question of the piston ring of to-morrow. The type which has a narrow face, bearing on the cylinder wall, and is bedded deeply into the piston grooves, is undoubtedly sound: not only does it reduce leakage through the groove round the back of the ring, as he states, but it also has a better chance of keeping the whole of its friction face bearing on the cylinder walls. This apparently small point secures rather important consequences. It prevents the exploding charge from blowing past the rings so readily, and it cuts down friction by eliminating the oil-wedging tendency, to which I recently drew attention. But the number and size and location of the rings, so far as future motor cycle engines are concerned, will depend enormously on the metals employed for pistons and cylinders. I think we may wash the obturator ring out: at its best it was an infernal nuisance, and it owed its genesis to the use of badly designed cylinders, which distorted atrociously—a fault which is now mastered. The motor cycle designer of the near future will not be afraid of distortion, but he may be troubled by his piston and his cylinder expanding in different ratios. He may be prepared to tolerate this varying rate of expansion, because of the improved cooling or reduction in the weight of reciprocating parts which it gives him. If he so tolerate it, he will have to take stringent precautions against gas blowing past his piston. Such precautions might take the form of a single ring, equipped with one of the modern "joints" which is not a "gap," as well as a joint—the ordinary 45° diagonal split, of course, was simply a gap. We can hardly speculate about the piston ring of the future, until we know of what materials the commercial motor cycle piston and cylinder will be. Personally, I am of opinion that it is not much use trying to cut down piston friction on motor cycles until we get rid of our crude lubricating systems. At present our pistons have to shoulder their way through a huge sludge of surplus oil. Given proper cooling, we shall not need a fifth of the quantity of oil. Given less oil, we can begin to talk of reducing ring friction.

The Ricardo Piston.

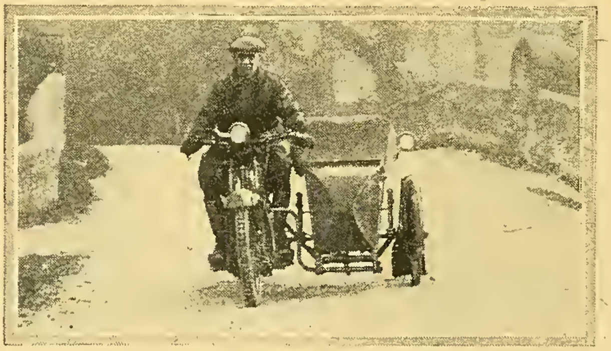
I DARESAY some of our readers have yet to strike the Ricardo piston, though they may be familiar with its name. The cognoscenti will forgive me if I explain its peculiarities. Everybody knows that when a cylinder wears in prolonged use it wears oval, instead of, *e.g.*, expanding an originally circular bore of, say, 85 mm. diameter into an enlarged circle of 86 mm. diameter. The reason for this wearing oval, of course, is that the crank pin travel subjects the front and back of the cylinder (when the crankshaft runs athwart the cycle) to far more pressure than the right and left-hand sides of the cylinder. The Ricardo piston has approximately the usual depth of skirt at its back and front, *i.e.*, on its "pressure" sides. But the skirt is cut away on the two non-pressure sides, so that on those sides there is no metal worth speaking of below the "land" on which the rings are mounted. This is an extension of an idea first applied to motor cycle engines, I fancy, by the Rudge people. They found that their early flush-sided pistons, which were very light, used to distort. So they recessed a broad waistband all round the skirt, with the result that if the waist distorted it did not touch the cylinder walls at any point. The patent Zephyr piston carried the same idea a stage further, for it had an hour-glass contour, and was an improvement on the Rudge: if a Rudge engine was over-oiled, the shallow recess in its waist simply acted as an oil trap, imprisoned a film of oil shaped like a napkin ring, and slid it up and down. These experiments gradually taught engineers that engines suffered much from two unsuspected causes of friction. The one was a sticky film of oil between the entire surface of a flush-sided piston and the cylinder wall, which had to be forcibly "sheared," and acted as a drag on the piston, even though it helped to keep things cool. The other was that piston rings might maintain compression-tightness, but they often served as oil wedges, too. The old flush-sided piston is as dead as a door-nail. The old heavy oil sludge will slowly follow it into oblivion. Alterations in piston rings will follow upon these changes, and are now only waiting—as far as motor cycle engines are concerned—for peace to determine our cylinder and piston metals. In which connection we must realise that the cast iron cylinder is also obsolete and past resurrection.

THE FIRST 1000 MILES on a MILITARY MODEL A.J.S.

Notes on the Running of a Popular Outfit.

EVERYONE knows that the A.J.S. is not a speed merchant's mount. With its sidecar attached, it is as fast as most riders require, pulls well on hills, is delightful to control, and requires no attention whatever. The aim of the makers has been to obtain absolute reliability, weatherproofness, and tractability—to produce a thoroughly serviceable mount which will meet with the thorough approval of riders of ordinary engineering ability. A noble attempt has been made at efficient mudguarding, and, except in the vilest of winter weather, one keeps spotless. When the roads are a-swill, however, nothing short of leg shield will keep one clean on any mount, and even with the A.J.S. sensible front wheel mudguard a certain amount of splash blows back on to the knees of the rider.

On first taking delivery of the new machine sundry carburetter adjustments, described later, were necessary ere it began to shed its lethargical attitude towards anything in the way of hard work. Then came a long run to the West of England and back, taken pretty well all out with a veritable rhinoceros and his luggage in the sidecar. This had the desired effect of freeing things up, and the engine began to take a new interest in life. Though its maximum is about 42 m.p.h. on the level, it will hold an average of 32 m.p.h. without great effort. In other words, and in common with one or two mounts of similar type, the A.J.S. is a slow machine on a short journey, but a fast machine on a long journey!



The military model A.J.S. on which the 1,000 miles test was accomplished.

I have always regarded the A.J.S. as rather under-engined for a heavy sidecar mount, but what it lacks in actual c.c. it makes up in what one might term "general pluck." No matter how hard and difficult the going, it is ever ready to get off the mark on its top gear immediately the severity of the conditions relents in the least degree, and normally it possesses a surprising degree of ginger in tackling gradients. The only time at which one becomes conscious of the engine being slightly on the small side is when carrying an extra heavy passenger in the sidecar. Every pound over 10 stone begins to tell on the gradients, whereas with an engine on or about the 1,000 c.c. mark it makes no perceptible difference to the road speed whether the passenger be 10 stone or 14 stone.

A 30 jet is used in the Amac carburetter, which is tuned for high "revs" and sturdy pulling rather than economy and a slow tick over, yet with passenger the petrol consumption usually centres about 78 m.p.g.

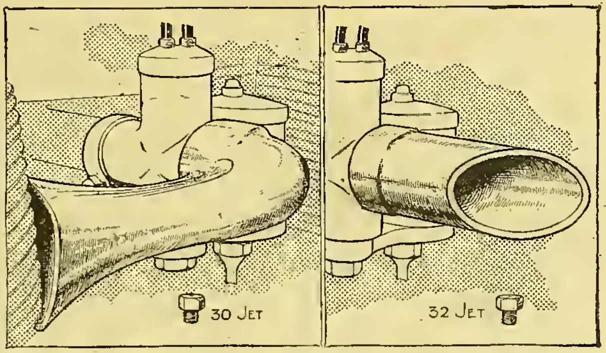
It may be added that, immediately after the ride to the West of England, the cylinders and pistons were carefully gauged, and were found to have retained their rotundity, the back cylinder being perfect, while the front was so slightly out of truth as almost to defy observation.

As turned out by the makers, the carburetter is fitted with a neat aluminium hot air intake, drawing its supply through the front cylinder fins. This is doubtless a wise provision, especially as the machines were designed for use in Russia, but a hot air intake on an air-cooled engine inevitably detracts from the

The First 1,000 Miles on a Military Model A.J.S.—

"revving" capabilities of the engine. This particular one was fitted internally with a double thickness of gauze, the disc being of rather narrow diameter, with the result that it simply did not admit sufficient air for high revs.—what little it did admit being expanded by the heat. The volumetric efficiency of the engine was thus knocked down, though by employing a small jet one could obtain marvellous petrol consumption and a beautifully slow tick over.

This, then, accounted for the sluggishness of the engine in delivery tune, and was possibly a state of affairs wisely arranged for the benefit of the hairy Cossack. I pulled out the gauze, and at once discovered that the engine would take no air at all. The next obvious thing to do was to fit a larger jet, and the thirty gave good results with the hot air intake fitted. When in a skittish mood I removed the hot air intake, fitted a rubber scoop to the main air supply, substituted a thirty-two jet for the thirty, and pulled out the two little extension pipes from the silencer. Result—colossal kick!



(Left) The A.J.S. hot air intake, which, used in conjunction with a thirty jet, gives ordinarily economical running. (Right) By fitting a rubber hose air scoop and using a larger jet more power and higher revs. are obtained.

It may be added that in tuning a carburetter, petrol level must be considered in conjunction with the size of jet used.

The engine has proved conveniently indifferent as to the fuel it consumes. On No. 2 petrol it invariably starts second kick after flooding. On half substitute and half petrol it is necessary to flood twice and kick four times. On one occasion I was reduced to paraffin with the merest smell of petrol—and that on a frosty night. After flooding six times and kicking sixty-two times, I induced a wayside watchman to lend me some of his coffee to pour over the induction pipe, after which the first kick did it.

A Mudguarding Indiscretion.

Though the chain cases permit a reasonable degree of accessibility, which is further added to by the system of interchangeable wheels, I cannot speak very highly of their weatherproofness. Recently, after a spell of abnormally muddy weather, the kick-starter threatened to strike work, so I removed the front cover to investigate. To my surprise both chains were dry of oil, while the front chain was literally wallowing in a stiff solution of mud and water—conditions infinitely worse than those to which a totally exposed chain is subjected. A considerable accumulation of stiff mud, through which the clutch sprocket had ploughed a groove, was removed from the inside of the cases, which were then washed out as well as possible, and a pound of stiff grease inserted.

This state of affairs was found to be mainly owing to an indiscretion in the design of the rear wheel mudguard—a point quite out of harmony with the general detail care and thoroughness exhibited in most minor points. The wide rear wheel mudguard overlaps the chain case, so that at the point at which they come in contact the torrent of mud from the inside of the guard naturally drains itself on the top of the case—and at its most vulnerable point—the thin slush percolating through the chinks and the joint through which the left chain stay emerges. The lip of the front chain case cover fits outside instead of inside, so that mud and water contrive to get through it, and at the top of the cover is a small recess in which quite a spacious puddle is free to collect, duly draining itself through the joint.

The more one has to do with chain cases the more convinced does one become that the only variety that warrants its existence is the cast aluminium type. However, by bending the guard so as to divert the stream of mud inside the case, the trouble referred to has practically been eliminated.

It is customary in these days to lubricate the chains by the overflow from the engine, but for some reason the A.J.S. people have eschewed this system. With a chain-cum-belt drive it certainly has its defects, but I see no objection to it when all enclosed chains are used, and the system tends to safety in the hands of the ordinarily forgetful rider. With the A.J.S. it seems to me the best plan is to cram handfuls of stiff grease through the observation holes at regular intervals, trusting that centrifugal force will keep the clutch plates fairly clear.

Features of the Military Model.

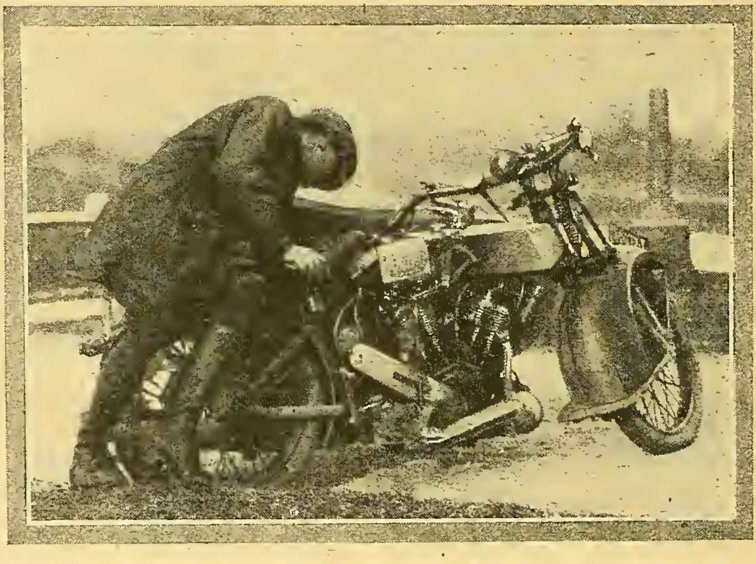
The mount is, of course, a Russian military model, having the increased ground clearance, 700 × 80 mm. tyres, and long magneto drive laid down by the Russian specialists. The last point is simply a polite way of asking for trouble in the direction of a slack magneto drive and worn bearings. The A.J.S. design was the result of a decade of experience, and one cannot help but feel that the authorities responsible for the change might have done well to consult the opinion of firms who knew their business before forcing them to undertake radical alterations in design. The increased ground clearance is a good point in this case, as it does not hinder the speedy removal of the cylinders, but, in company with the large, squashy tyres, it renders the machine rather an unpractical proposition for solo use. Coventry possesses a highly efficient brand of grease of its own, created by the incessant flow of traffic necessary for the distribution of thousands of copies of *The Motor Cycle* and its sister journals, and riding the A.J.S. solo over the tramlines proved an undertaking eminently suitable for contortionists and acrobats.

The large wheels and tyres are, however, a huge acquisition over present-day roads. One can ride fast over the potholes without experiencing the least discomfort, the spring forks functioning excellently, and with sidecar attached the propensity towards sideslip does not matter in the least. The rear brake of the A.J.S. is rightly famous.

The First 1,000 Miles on a Military Model A.J.S.—

The engine of the A.J.S. is remarkably silent, both as regards valve mechanism and exhaust. There is none of that deafening valve clatter at high speeds common with many twins, and when throttled down in traffic the engine runs like a Rolls-Royce. It is a highly desirable type of mount for every class of rider who delights in smooth running, reliability, and an absolute no-trouble mount. The clutch is one of the kindest I have handled. It is difficult, indeed, to obtain anything but a smooth engagement, and being adjacent to the rider's hand it can be utilised as a shock absorber at low speeds.

It will be recalled that the A.J.S. people abandoned the use of the engine-shaft friction shock absorber (fibre to metal) on account of the fact that they discovered its correct adjustment caused more trouble to "the average rider" than its existence warranted. This may have been a wise step, but at the same time there is no getting away from the fact that a friction shock absorber is highly desirable with a positive transmission, and though on wet roads its necessity is not felt, the drive is inevitably harsh without it on dry roads. The idea of using the clutch instead is perhaps simple, but it must be borne in mind that one generally forgets to use the clutch till the snatchiness of the drive warns one to do so, by which time the worst snatches have probably been delivered and the necessity of a shock absorber is diminishing. Moreover, it is not a difficult matter to arrive at a spring friction shock absorber which requires no adjustment whatever—is, in fact, unadjustable.



Adjusting the carburetter. The picture prompts the question which many sidecarists have put, "Why are parts which need adjusting placed on the inaccessible side of the machine?"

The Thomson-Bennett magneto is a fine instrument, which contributes largely to the characteristically easy start obtainable. The engine will start even when so stiff that one can hardly kick it over compression, and on coal gas can be throttled down to a scarcely audible tick.

The Mills-Fulford "Corvette" sidecar is comfortable and well sprung—an excellent piece of work which demands only a spring luggage grid. The windscreen first fitted got rather into the way of the wide semi-T.T. bars, so it was removed, whereupon we discovered that with the hood erected the passenger was much better sheltered without the screen than with it. In fact, it was a doubtful blessing at any time, the hood fully meeting requirements in wet weather, and it may be added that the sidecar rides much more comfortably with the hood erected than with it down—the hood steadying the rebound. This points to the desirability of yet another friction shock absorber.

A Ward and Goldstone accumulator lighting set was installed, but since this has already been fully described it may be passed by with the comment that it has proved entirely satisfactory, and gives sufficient light for war-time requirements. The Bonniksen speedometer is an excellent instrument of infallible accuracy. It registers the exact m.p.h., even when one is pushing the machine across the yard into the garage, while it is a huge advantage at high speeds to enjoy the facility of reading an absolutely stationary needle, which hits the mark and stays there for a few seconds, till its place is taken by its neighbour.

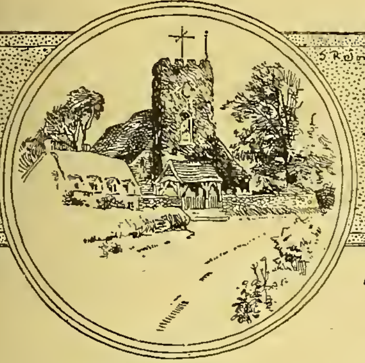
A Few Candid Criticisms.

It will be recalled that in the latest model A.J.S. a truly triangulate frame construction is employed, and this excellent feature necessitates the flat-topped tank with its cleanly exterior, there being no top bar under which dirt and oil can collect. Incidentally, no petrol gauge is necessary with this type of tank; when only half a gallon is left it gives off a faint base rumble, which I have mistaken for an aeroplane passing near, and as the supply sinks to a quarter-gallon the sound is reminiscent of a boy scouts' band in the far distance.

I have no intention, and there is certainly no need, to sing the praises of this world-renowned machine, so now for a few criticisms. The foot plates are a shade too far forward for long-distance riding, with the result that one acquires the habit of sitting with one's instep on the elevated heel, which is bad for the instep, and worse for the side of one's boot, which is constantly chafing against the jagged points of the clutch-operating mechanism. No doubt by curling one's foot in a special way one can avoid the mishap, just as, I have heard, one can drink paraffin without nausea by curling one's tongue in a special position, but—why drink paraffin?

War-time tank stoppers leak enough petrol to run an Auto-wheel, and, as for war-time toolbags——! But the A.J.S. is a thoroughly sound mechanical job, the workmanship and design being of the highest order, and obviously the result of long experience among practical riders and engineers—facts which are perhaps proved by the high second-hand value these machines maintain—a sure indication of the public attitude towards them.

CHINOOK.

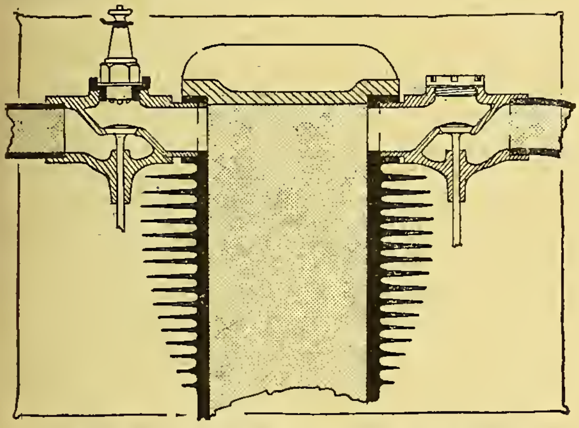


A SYMMETRICAL CYLINDER

How to Avoid Heat Distortion.

THAT advantages would accrue from having a plain symmetrical cylinder instead of the accepted lop-sided arrangement has long been admitted.

The cylinder with overhanging valve pockets is liable to distortion during casting, and when in use under severe conditions, and with the unequal distribution of heat which always obtains, distortion in a greater or less degree is certain.



Detachable valve pockets, to be screwed or bolted on the cylinder casting.

Yet notwithstanding the fact that all these things are perfectly well known, little, if any, alteration to design has resulted. It is not, of course, possible for any radical departures from usual practice to take place until after the war is over. The point which interests us, however, is, Will there be an alteration in design after the war, or has finality been reached in this direction?

One is probably safe in saying that as regards distortion and overheating of the exhaust valve the cylinder with overhead valves comes out better than the side-by-side type.

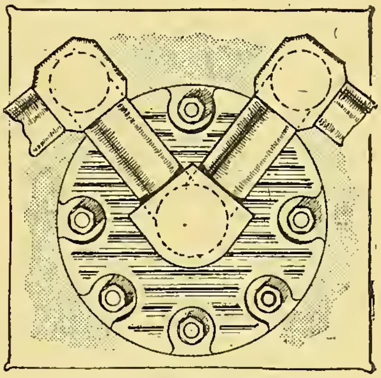
Similarly, cylinders fitted with concentric valves and a movable seat, as illustrated in *The Motor Cycle* some months ago, would be a still greater improvement. This type of engine, however, does not seem to materialise in practice.

Following the above, the Blackburne would appear to be a considerable advance over the old design of engine.

If the subject is studied further one inevitably comes to the conclusion that the only method of obtaining a clean and symmetrical cylinder is to detach the valve pockets and make separate castings of them.

Detachable Valve Pockets.

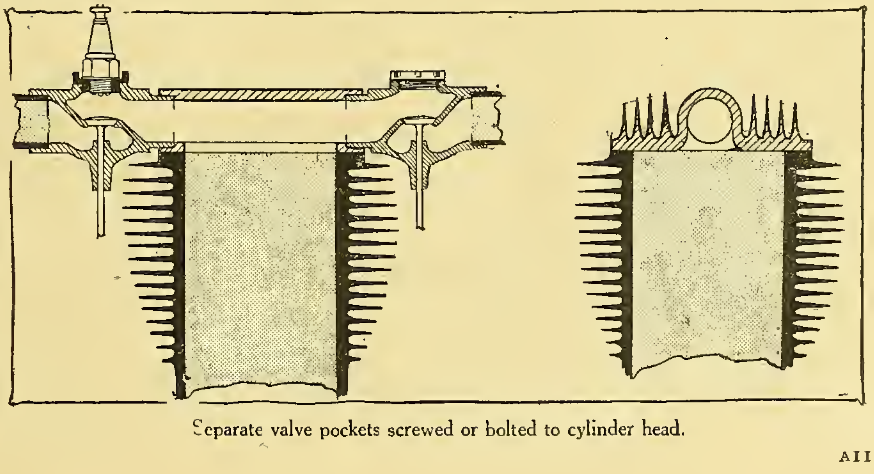
Diagrams are here given showing what would be the result of doing this. There are a few points which it may be wise to notice. The valves and pockets may be placed in a number of alternative positions, according to the wish of the designer, either to suit his valve gear or to obtain a preconceived method of heat distribution. With regard to the latter, for instance, there are certain attractions about putting the inlet valve on a level with the top of the piston when it is at the bottom of its stroke, thus introducing the cool mixture to the centre of the cylinder and on to the top of the piston head.



Plan of an arrangement which lends itself to existing valve gear.

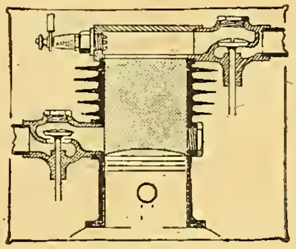
As regards the construction of the valve pockets, it may be found that these can be made of a lighter yet stronger material than cast iron.

It will be seen that an advantage would be that one could carry a spare valve pocket and valve complete. The latter would be already ground in, and a change could be made on the road, or at any time, and the old valve and pocket reground comfortably at the bench.



Separate valve pockets screwed or bolted to cylinder head.

A Symmetrical Cylinder.—In the diagrams a detachable cylinder head has been shown allowing easy access to the cylinder and piston for decarbonising purposes. The valve pockets could be used, of course, with an ordinary closed cylinder. The exhaust valve would be subject to a maximum of cooling by reason of the exhaust valve pocket being practically surrounded by fresh air, and it might be assisted by the addition of radiator fins to the valve pocket.



The alternative position for the inlet valve referred to on previous page.

As regards manufacture, one would think that an engine with detachable valve pockets would be turned out cheaper in quantities than would an engine with pockets cast integral with the cylinder.

Certain practical objections may be raised to this system of arranging the valves, but there is no doubt that any manufacturer convinced of the advantages to be obtained would make short work of these.

ENGRO.

AMERICAN RECORDS IN 1917.

Interesting News of American Motor Cycling Events during the Past Year.

OUR American correspondent, in sending the compiled motor cycle records in the United States for last year, prefaces them with the following characteristic comments, which read truly American:

"You may take it from me you will not see much more activity in motor cycling until the curl has been taken out of the Kaiser's moustache.

"We surely are getting into our stride over here, and profiting by your mistakes, most willingly pointed out to us; we are speeding up by the minute. If I could but tell you all that you may see—but it's best to keep quiet: we've too many Huns over here with ears cocked to the windward for stray bits of information now.

"Wait until we get our first casualty lists—we're gonna see some damage done the lukewarm Toots in our land as sure as gun's iron. Damit! we let 'em print and talk German yet, but it's gonna stop—wonder if these sentiments are too much red-fired stuff?" It is good to hear that the U.S.A. are getting into their stride; there is consolation, too, in the fact that someone will profit by our mistakes, though there is irony in the statement.

LONG DISTANCE AND TWENTY-FOUR HOUR RECORD TRIALS IN UNITED STATES, 1917.

January 3rd-4th.—Roy Artley (Henderson sc.), 707 miles in 21h. 18m. over 108 mile course on public highway in California. Average, 35 m.p.h.

March 1st-2nd.—Don Johns (Indian sc.), 797 miles in 22h. 27m. over 90 mile course on public highway in California. Average, 35.35 m.p.h.

March 26th-27th.—Alan T. Bedell (Harley-Davidson solo), 1,000 miles in 20h. 42m. 30s., 1,153.5 miles in 24h., on Ascott Track, Los Angeles, California. Average speed, 48.06 m.p.h.

June 8th-9th.—Lt. E. F. Hoffmann, U.S.A. (Indian sc.), 963.6 miles in 22h. 0m. 4s. over 20 mile course, El Centro, California. Average speed, 43.68 m.p.h.

June 5th-13th.—Alan T. Bedell (Henderson solo), Los Angeles-New York City, 3,296 miles in 7d. 16h. 16m., breaking Baker's Indian record by 92h. Bedell rode 127h. 46m., averaging 25.8 m.p.h.

June 19th-20th.—C. F. Bruschi (Harley-Davidson sc.), 1,000 miles in 20h. 39m. over 20 mile course, El Centro, California, averaging 48.42 m.p.h.

June 26th-27th.—E. G. Baker (Indian solo), 1,386.25 miles in 24h., 1,000 miles in 17h. 26m. 30s., 500 miles in 8h. 38m. 31s. Average speed, 61.79 m.p.h.

July 17th-20th.—Roy Artley (Henderson solo), Three Flag Record, Blaine, Wash., to Tia Juana, Mex., 1,667 miles in 72h. 25m., breaking Baker's Indian record by 8h. 50m. Artley made continuous ride record of 34h. 45m. Average speed, 23.01 m.p.h.

July 19th-20th.—"Red" Parkhurst (Harley-Davidson solo), 1,452.75 miles in 20h. 15m. on Sheepshead Speedway, 1,000 miles in 17h. 8m. 28s., 500 miles in 7h. 35m. 17s. Off track 2h. (rain). Average speed, 72.24 m.p.h.—Otto Walker (Harley-Davidson sc.), 1,158.75 miles in 22h. 36m., 1,000 miles in 20h. 22m. 46s., 500 miles in 9h. 47m. 4s. Average, 48.54 m.p.h.

August 14th-15th.—E. G. Baker (Indian solo), 1,534.5 miles in 21h. 37m. on Cincinnati Speedway, 1,000 miles in 16h. 14m. 15s., 500 miles in 6h. 59m. 15s. Average, 70.9 m.p.h.—Teddy Carroll (Indian sc.), 1,275.9 miles in 24h., 1,000 miles in 18h. 48m. 20s., 500 miles in 8h. 56m. Average speed, 53.6 m.p.h. (These are the highest figures over the twenty-four hour route to date.)

September 11th-13th.—Jos. B. Werner (Harley-Davidson sc.), New York-Chicago, 932.6 miles, 44h. 14m. Average speed, elapsed time, 20.55 m.p.h. Werner holds continuous driving record of 44h. 14m.

September 20th-26th.—E. G. Baker (Indian solo), New York-Los Angeles (failed), 2,755 miles in 5d. 8h. New York-Indianapolis, 802 miles, 22h. 10m.

November 15th-17th.—E. T. Buck (Indian sc.), New York-Chicago, 932.6 miles, 43h. 20m. Both this and Werner's ride were continuous drives.

November 20th-21st.—G. C. Austin (Cleveland lightweight), Seattle-Everett, 32 mile course, 542.4 miles, 20h. 26m. Rain and fog. Average, 26.25 m.p.h.

December 5th-6th.—Albert Burns (Indian lightweight), Seattle-Everett course, 552 miles, 23h. 43m. Average speed, 23.24 m.p.h. Worse weather conditions than previous attempt.

THE PRICE of THE MOTOR CYCLE *NOW RAISED TO THREEPENCE.*

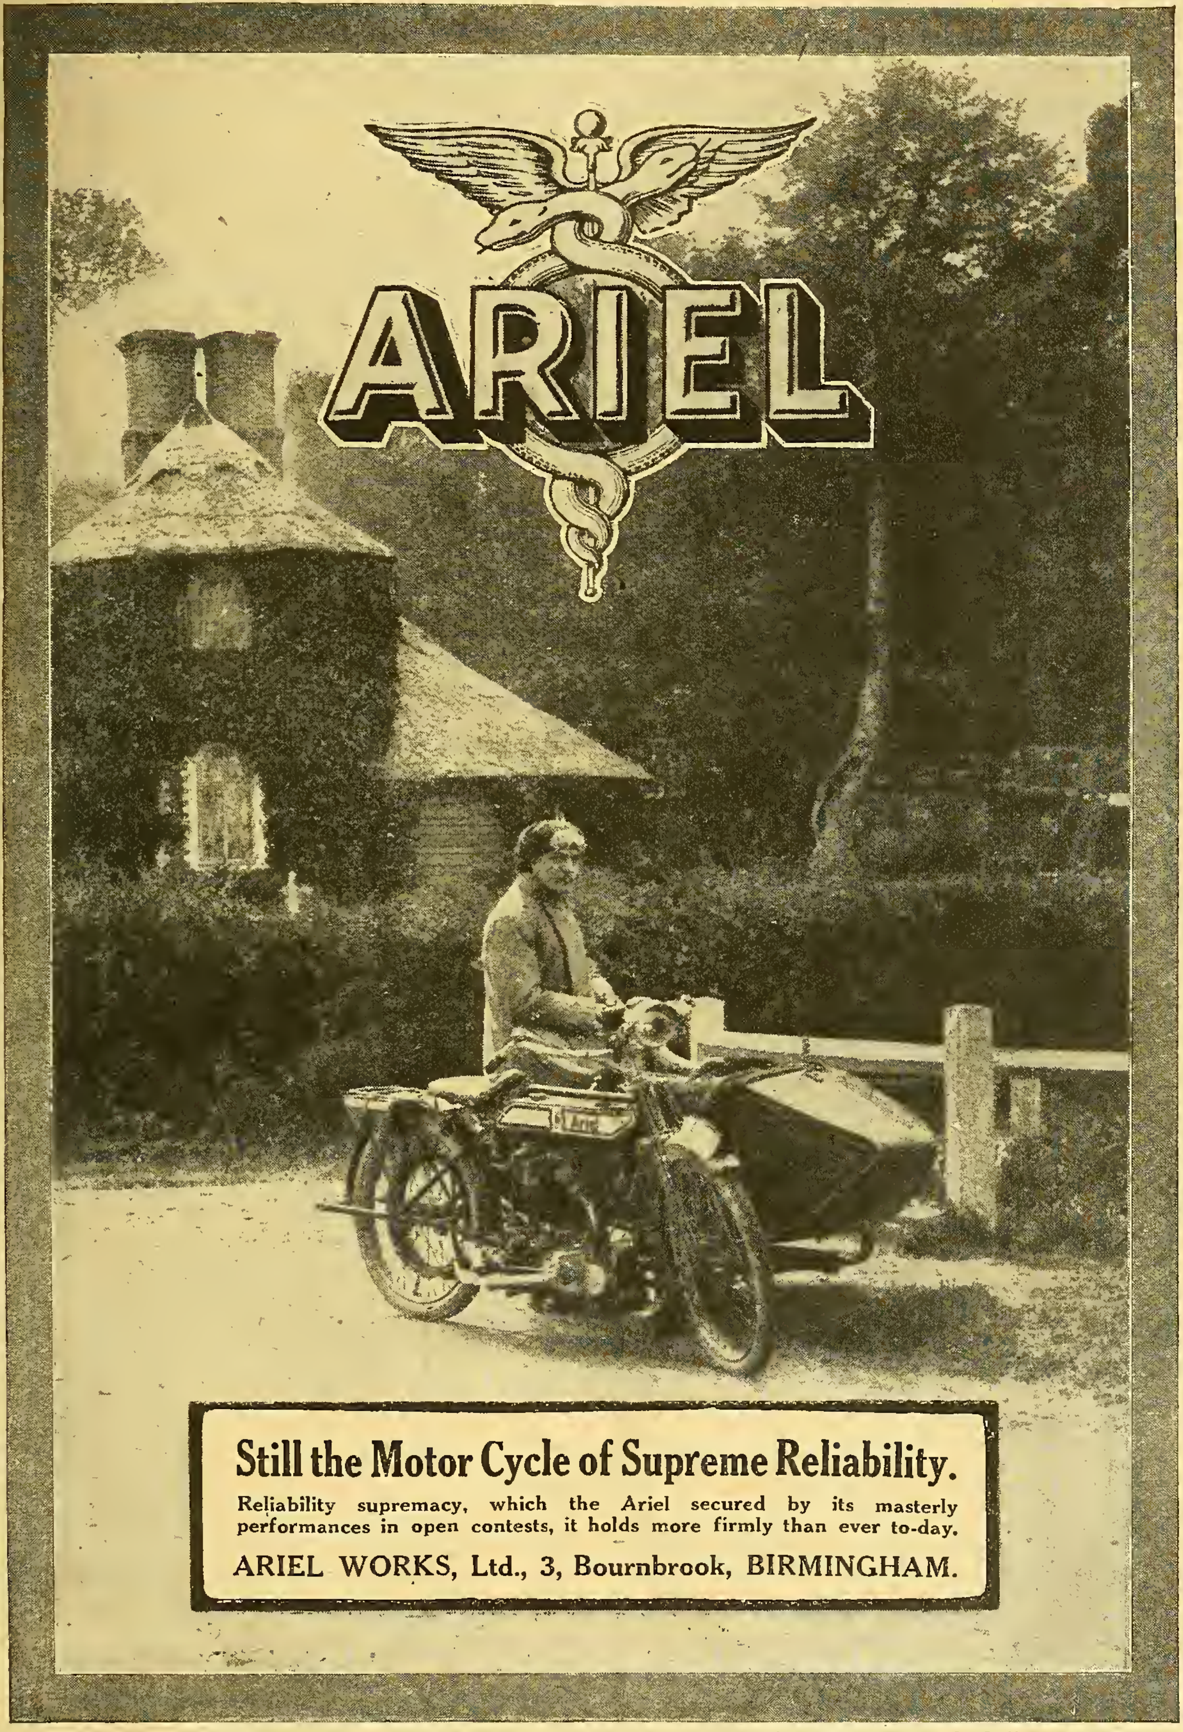
Commencing with this issue the price of "THE MOTOR CYCLE" is raised to 3d. a copy.

This further increase is necessary owing to the drastic restriction imposed on the import of paper and paper making materials during 1918 and the consequent heavy advance in the cost of paper, but the price will be reduced as soon as circumstances permit.

The subscription rates are correspondingly raised on renewal or to new subscribers:

British Isles .. .. 15/2 per annum, post free
All countries abroad.. 19/6 " "

All subscriptions current at the time of reducing the price will be proportionately lengthened for the benefit of each subscriber.



Still the Motor Cycle of Supreme Reliability.

Reliability supremacy, which the Ariel secured by its masterly performances in open contests, it holds more firmly than ever to-day.

FLYING FACTS AND THEORIES

A REPLY TO FURTHER CRITICISM.

By W. G. ASTON, A.M.I.A.E.

I HAVE to thank several correspondents for their appreciative criticism of my articles, especially the writers of the three letters in the issue of *The Motor Cycle* for January 24th. In the same issue a further article appeared entitled, "The Feel of the Machine," which to a certain extent answers most of the points raised, but the matter is of sufficient interest, I think, to justify a reply *seriatim et privatim.* First of all, I would wish to point out that this heading, "The Feel of the Machine," is a quotation, and, in point of fact, is an expression with which I find it difficult to agree. My question, "After all, what *is* the feel of the machine?" is scarcely answered by "Jacobus, R.F.C.," who writes very interesting and informative details concerning the *feel of the pilot,* which, I would submit, is a distinction with a difference, though I will not deny that "O.J.F.S.," "Jacobus, R.F.C.," and myself are all referring to one and the same thing.

The important point, however, is this, that this "feel" is entirely dependent upon the sensitiveness of the aviator, and, therefore, involves a personal equation which cannot be accurately recorded for purposes of reference. Thus one will find a machine damned by a pilot because it is "heavy on the controls," whereas another will equally strongly, and equally credibly, assert that it is "light on the controls." It is always desirable to avoid inexactitudes of this nature, and for that reason I feel that it is probably better, during the training of a pilot, that he should learn to associate his sensations with the readings of an invariable instrument such as a "bubble," since this association will become a sort of natural calibration. I am well aware that a good pilot is perfectly at home, in most circumstances, on a machine entirely innocent of instruments, but such "stars" are generally men of unusually keen perception, and cannot be regarded as the rule. My own personal view is that the average pilot flies better with instruments than without them, though in this I am very likely at variance with better qualified opinion.

Sensations during a Turn.

As "Jacobus, R.F.C.," pointed out, putting into different words the same thing that I had said in another part of the same issue of *The Motor Cycle,* "If the turn is correctly carried out (*i.e.,* correct proportion of rudder and bank), the pilot experiences a sensation of being pushed hard against his seat." It is for this reason that an aeroplane tends to stall more easily on a turn than when flying straight. If the pilot presses more heavily on his seat, the seat must obviously press more heavily on the aeroplane, and the same applying to all other weights supported in it, it follows that the total effect is that the aeroplane presses more heavily on the air. In other words, its effective weight on a turn is greater, owing to centrifugal force, than when flying straight. That being the case, one of two things must happen if the speed of the machine is to remain constant. Either more thrust must be obtained from the engine or the requisite energy must be obtained, by a loss in altitude, from the only other source, namely, gravity.

If both the same height and the same speed are demanded on a turn as on a straight, then the engine *must* be opened up—there are simply no two ways about it.

Stalling is more likely to occur on a turn because of this centrifugal addition to the weight of the machine. If weight is increased and speed kept constant, the angle of incidence of the main supporting surfaces must be proportionately increased, so that a greater volume of air per unit of time may be accelerated downwards. The object of a curved-section lifting surface is to coax the air to follow the upper surface (from which the greater part of the lift is derived), as well as to force it to follow the lower surface. This idea is illustrated in the accompanying diagram, fig. 1.

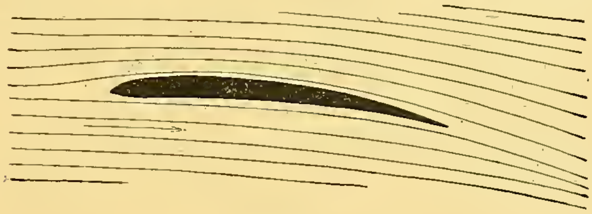

Fig. 1.

"Dead" Air.

Now, if the angle of incidence be increased, the air will have more and more reluctance in following the curvature of the upper plane surface, until a point is reached when the flow ceases to be continuous, and large surfaces of discontinuity are formed. This is shown in fig. 2. The dotted area represents a region of "dead" air, which tends to make a wake behind

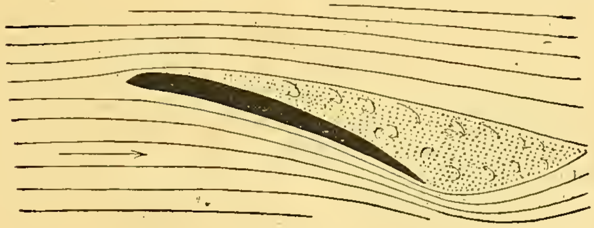

Fig. 2.

the plane, and is full of eddies and turbulence. When this discontinuous flow takes place, it has two immediate and important effects. Firstly, it enormously increases the resistance of the plane; secondly, it equally greatly decreases the lift. The result is that both factors mutually support one another in reducing the speed of the aeroplane, to counteract which it is forced to dive earthwards in order to regain the necessary supporting speed. A third result of the lack of uniformity in flow is that the centre of pressure, *i.e.*, the point through which the lift force is considered to be acting, instead of having a definite position along the section, becomes very indeterminate, and, further, small changes in angle of incidence are liable to cause large changes in its position. This means that when a machine "stalls" it is impossible to get control over it with the usual organs—rudder, elevator, and flaps. In fact, until the centre of pressure becomes fairly determinate in position, the aeroplane may be said to have a total lack of any directive sense, and, consequently, simply drops until sufficient air reaction is set up to provide forces whose effects can be dealt with by the ordinary means of control.

It is for this reason that executing turns near the ground with a failing engine is so dangerous, having regard to the fact that, if a stall occur, there is insufficient room for the aeroplane to perform its act of recovery. Given sufficient height above the ground, no manœuvre or evolution whatever need be a source of danger, provided always that strains beyond the strength of the machine are not imposed.

Flap Resistance.

As I showed in the original article which has evoked so much criticism, to turn "up wind" is likely to make the pilot think he is underbanking. His tendency will be to overbank, therefore, and, in addition, to make a very sharp turn, which, by increasing the load on the wings, is liable to promote a "stall."

"L.B., R.A.M.C.," mentions that on a turn an aeroplane will demand more power to keep it at a definite speed, since the altered position of the ailerons ("flaps" is a much better word, though I understand the other is officially more approved) imposes an additional resistance to motion. This, to a certain extent, is true, but it is a secondary effect only, and, therefore, I did not deal with it in the original article. In aeronautics one subject is often very intimately related with another, and consequently, with a limited space at one's disposal, it is very difficult—nay, impossible—to deal with one particular consideration and all its connections, hence secondary effects have sometimes had to be temporarily ignored.

The question of flap resistance is not necessarily raised in this case, because it is perfectly easy on a stable machine to make turns without interfering with the flaps at all—lateral stability (as dictated by suitable fin and body area) looks after the "banking," and the pilot has only to operate the rudder—these organs being called into action only in case quick turns are demanded. Thus, in a large number of machines, as many of my correspondents are aware, the passenger is furnished with sufficient dual control to let him take charge in case of need, but this control only relates to the rudder and elevator.

As far as flaps are concerned, since these do not give a truly helical formation to the main plane, I think it may be admitted that they, inevitably, must result in greater head resistance, but it is by no means so obvious that the same is the case with a properly designed wing-warping arrangement. It is true that, whilst the drag of one wing is increased, the drag of the other is proportionately decreased, and there is no gain in that direction, but, on the other hand, the two wing tips have different speeds, though their *average* speed is that of the centre of gravity of the machine as a whole. In this connection, therefore, it is a question of how much the warping alters the lift-drag ratio at various points along the wing. I *think* that here the warping idea possesses a certain advantage, but constructionally it is inferior to the flap.

Mr. W. T. Langman disposes of the question of turning "up" and "down" wind with a brevity that is admirable.

Returning to the question of turning, here is a proposition. Given two exactly similar machines, which start from the same height with the engine cut off, and which are to touch ground with the same landing speed (wind neglected); which will get to earth first, that which descends (part of the way) in a spinning nose dive, or that which descends with a straight dive? I shall look forward with great interest to solutions of this problem from practical pilots.

DEATH OF MR. H. WALTER STANER.

A Severe Loss to "The Motor Cycle."

It is with a sense of sorrow and sincere regret that we have to announce the death of Mr. H. Walter Staner, editor of *The Autocar*, and supervising editor of all Iliffe and Sons' motoring publications. Mr. Staner has been on the staff of *The Autocar* since its foundation in 1895, prior to which he was on the staff of *The Cyclist*. Having been responsible for the paper for the preceding twelve months, he became editor of *The Autocar* in 1901, since which time he has held a highly influential position in the sphere of engineering journalism. His name has carried great weight on mechanical matters throughout the motor industry, and the news of his sudden death will come as a painful surprise to his very wide circle of friends.

Three weeks ago a severe cold, from which Mr. Staner was suffering, developed into pneumonia, and the position rapidly became critical. The crisis, however, was safely passed, but on Sunday last complications became evident, and just after midnight he passed away.

No one knew Mr. Staner better than his own colleagues, who, apart from absolute confidence in his sound judgment, never found him too busy to discuss and assist in matters even most remotely concerned with business. In all one's dealings with him one was conscious of the most kindly and courteous consideration, for he possessed to an unusual degree the happy manner of conducting all business matters on the lines of friendly discussion.

Mr. Staner was a member of the R.A.C. Committee, and also an honorary member of the Institution of Automobile Engineers.

MILITARY NOTES.

The Best Platoon Leaders: Saving a Damaged Aeroplane.

PROMOTION.

WE are pleased to learn that Capt. B. C. Barton, formerly a member of the committee of the Public chools M.C.C., and now serving in the I.T., A.S.C., has been promoted to the nk of Major.

D.C.M. FOR BRAVERY WITH THE TANKS.

CPL. D. C. JENKINS, Tanks Corps, North Kensington, has won the D.C.M. When his officer was illed he kept his Tank in action with kill and gallantry until it was buried. Ie then took out all his crew and guns nd, placing some on the top of the ank and some on the ground, opened re on the enemy and prevented them rom advancing.

ROM ONE TANK TO ANOTHER.

WHEN casualties occurred in his Tank under very heavy shell and machine gun fire, L.-Cpl. E. agger, Tank Corps, Levenshulme, transferred a wounded member of his crew o another Tank. He also gained the .C.M. for his heroism.

SAVING A DAMAGED AEROPLANE.

TO save an aeroplane which fell between our lines and those of the enemy, Lt. Cuthbert D. Fellowes, R.F.C. and Yeomanry, who was awarded he Military Cross, twice crawled over hree hundred yards of open ground in ull view of the enemy, started up the ngine, and, lying flat on the ground, llowed the machine to pass over him. He then ran after it and gained the ilot's seat. The machine left the round, and, although the controls had een shot away, he shut off the engines nd steered it out of the range of the nemy's guns.

AIRMAN'S FINE FEAT.

SEC.-LT. ROBERT N. HALL, R.F.A. and R.F.C., attacked three enemy pilots, bringing two down in flames and leaving the third on fire. To accomplish this, he crossed the lines at a height of twenty feet, his machine being severely damaged by machine gun fire. He was awarded the Military Cross.

THE BEST PLATOON LEADERS.

MAJ. DAVID DAVIES asked in the House recently whether, owing to the large number of candidates sent home from Overseas for admission to officer cadet units, candidates from home sources are not accepted, save in special cases.

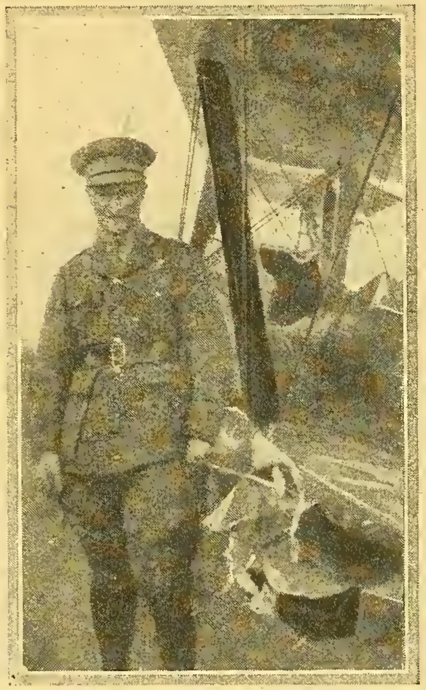
Mr. Macpherson's answer was: Preference is naturally given to candidates who are recommended while serving in the face of the enemy. Recently the course of training in cadet units has been lengthened; consequently it has been found necessary to cut down the numbers accepted. It is felt that candidates who have shown the qualities of leadership in the field will be readily selected for corporal's rank, and these are the men to train for the position of platoon leader. We have found that, as the war proceeds, we are able to raise our standard owing to the experience gained as non-commissioned officers by candidates for commissions.

A PILOT MOTOR CYCLIST.

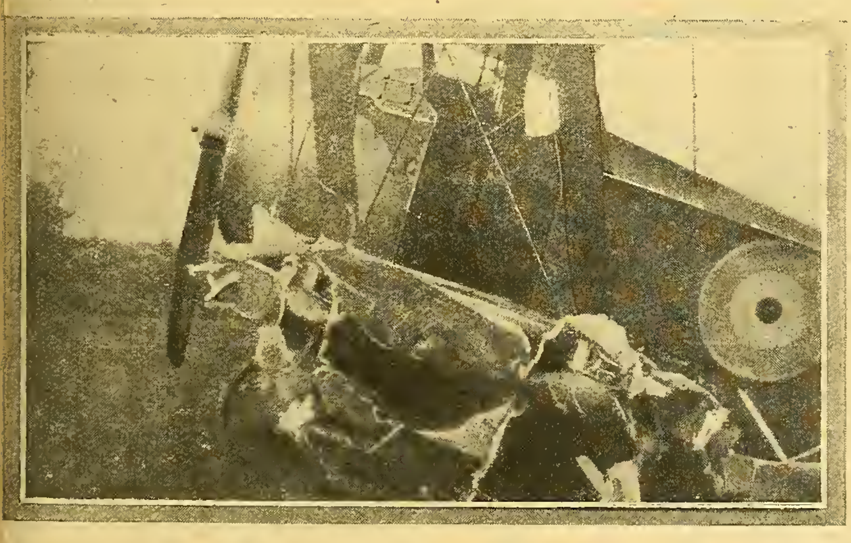
WE recently had a letter from F. M. C. Houghton, who was the originator of the successful naval and military race meetings held at Brooklands in 1915. In those days Houghton was in the Cyclist Corps, but later on became attached to the R.F.C., and after serving as an observer succeeded in getting his wings, which he did in the excellent time of two months.

Writing to us, he says: "Do you know, I had a collision in the air? It occurred at the end of October, while having a practice scrap with another pilot. He did not pull out of his dive quickly enough (he was on my tail), and would have crashed into me more than he did, only I happened to see him coming and did my best to avoid him. I partially succeeded, but, all the same, he had the bad taste to remove my lower port aileron wing tip with his air screw. I went down in a violent hurry, but managed after a bit to slow her down as gently as I could, suffering much apprehension as to whether and when my left wing would fall off and finish my career. Meanwhile, the other fellow glided off home unhurt. Luckily, I saw him, but he did not see me, and thought me a 'gonner,' as he believed he had hit me full amidships. I made a perfect landing, found a bicycle, and beetled off home. They all thought me a corpse. Tut!"

Referring to his last crossing Overseas, he writes: "We came over the night of that gale, and we knew all about it, too! There was a nasty wind from the starboard, which made us fly 'left wing low' all the way. The waves were so high that several times they came right over the upper deck; then I was pleased with my leather coat. Sometimes it seemed as if we should never gain an upright keel, and I had a colossal wind up. People were sliding right down to the rails, and there were some poor little W.A.A.C.'s on board, for whom I was jolly sorry."



After a collision in the air. The pilot is Lt. F. M. C. Houghton, who organised the successful Naval and Military motor cycle race meetings at Brooklands in 1915.



A near view of Lt. F. M. C. Houghton's damaged aeroplane.

Compulsory Digging.

There will be Association football and compulsory potato digging at Eton this half, says the *Eton College Chronicle*.

English Machines for Portuguese Army.

The Russian collapse has released many motor cycles for the civil market, but not all those built to the Russian specification. Royal Ruby machines of this type, however, are now being used by the Portuguese troops in France.

Occupations for Discharged Soldiers.

Discharged soldiers engaged in any one of the following occupations will be regarded as undertaking work of national importance: Shipbuilding, ship repairing, marine engineering, munitions, agriculture, agricultural implement making, food production, railways, tramways, iron ore mines, gas, water, electric undertakings; other work granted priority by the National Labour Priority Committee.

Home Production of Fuel Oil to be Increased.

In the production of fuel oil from home resources recently, the existing plants at the shale works in Scotland and the gasworks and coke ovens throughout the country are being pressed to their full capacity and are being extended. Retorts are to be used at the gasworks rather than the collieries, because labour, machinery, and experience are available at the gasworks.

Mails Lost at Sea.

The Postmaster General announces the loss, through enemy action, of mails despatched on January 24th for Salonica, Egypt, the Mediterranean, and British troops in Italy, containing letters, etc., for the Italian Expeditionary Force, Salonica Force, Corfu, Malta hospitals, and the Egyptian Expeditionary Force, which reached the Army Post Office, London, for despatch between midnight, January 21st, and midnight, January 23rd; letters, etc., for the Greek Post Office, Salonica, Malta Civil Post Office, the fleet at Malta and in the Eastern Mediterranean, and the Egyptian Civil Post Office, which reached the General Post Office, London, between 10 a.m., January 22nd, and 10 a.m., January 24th; also parcels for the hospitals and fleet at Malta and the fleet in the Eastern Mediterranean which were received in London between January 21st and 24th.

Coal Gas Equipment.

One Manchester firm which has laid itself out on a large scale for the equipment of coal gas containers finds itself with £1,000 value of bags on its hands as a result of the latest Order.

Second-hand Trade.

Strange to say, most of the large dealers in Birmingham and Manchester are fairly satisfied with present business, things being better than "one would expect."

Transport Board's Task—Eliminate Waste.

Mr. F. G. Bristow, secretary of the Commercial Motor Users' Association, says: "My association has offered its services to the new Transport Control Board. We have fifteen years' experience. No doubt the Board will first co-ordinate the road transport system and eliminate wastage."

To Protect the Interests of Motorists.

A meeting of members of the press and those interested in the motoring movement was held at Frascatti's restaurant on Friday afternoon last at the invitation of Mr. Arthur Goodwin, of Messrs. C. A. Vandervell and Co., in order to secure justice for all motorists, whether motor cyclists, light car owners, or owners of industrial vehicles.

The views expressed by the various speakers indicated that joint organisation of and joint action between existing motoring organisations was essential. It is to be hoped that the views expressed will help to promote the United Council of Motoring Organisations, mention of which has been made on previous occasions.

Coal Gas in Manchester.

A member of our staff says he recent
saw more motors in one day in Ma
chester than in a whole week in Covent
and Birmingham together, and two o
of three had gasbags on top.

Economy in Use of Motor Vans.

Applications for permits for new mot
vehicles to take the place of existi
vehicles cannot be granted unless it c
be proved that the use of a motor vehic
is absolutely essential in the nation
interest, and it is not possible to obta
a second-hand substitute.

Uniform in Mercantile Marine.

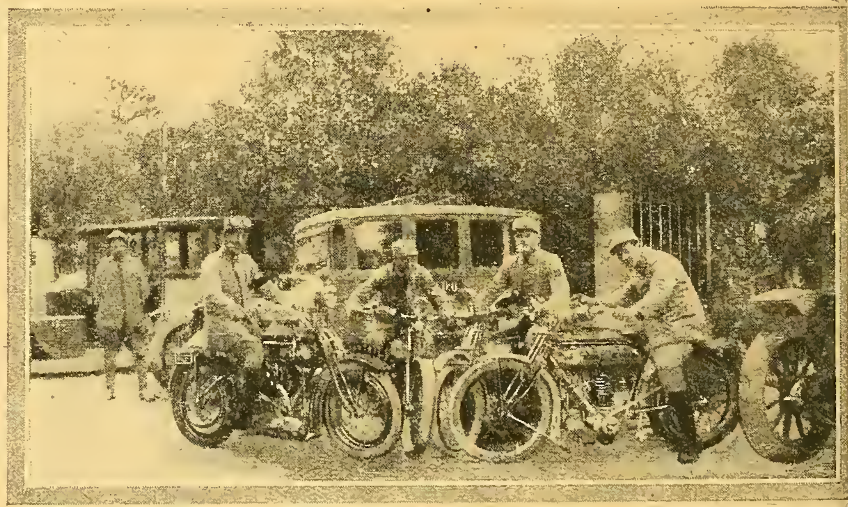
Agreement has at last been reached
the question of a standard uniform f
the mercantile marine service. An attra
tive cap badge for the standards h
been designed, consisting of a crown an
certain emblems expressive of the se
surrounded by oak leaves.

Prosecuted for using Gas.

George Weston, chauffeur, and Joh
Thomas Duncan, of Cardiff, who we
charged with using gas for the drivin
of a motor car to a meet of the Lla
gibby Hounds, were at Cwmbran (Ne
port) Sessions recently ordered to pa
the former £2 and the latter £10. Th
was the first prosecution of the kind.

An Extraordinary Flying Story.

We can vouch for the truth of th
following aeroplane story, incredib
though it sounds: An air mechanic wa
swinging a prop when the engine bac
fired and struck the back of his head-
the result was a broken prop and a ma
laid up for twenty minutes only, wit
not even a broken skin!



D.R.'s of the French Army mounted on Triumph and B.S.A. motor cycles. At the rear are cars belonging to the staff.

Footballs for Overseas.

The Director General of Voluntary Organisations has received from Mr. Barclay Walker generous gifts, including two hundred footballs, for distribution to the troops serving Overseas.

Petrol Supply and Storage.

The possession by a motor cyclist of motor spirit (said Sir A. Stanley) obtained under the authority of a motor spirit licence does not render him liable to penalties for hoarding, provided he complies with the provisions of the Petroleum Acts regarding storage.

Car Gas from House Main.

Major Huth, Second in Command of the Military Detention Barracks, Farnborough, was fined £9 and £3 3s. costs for disconnecting a pipe outside the gasmeter of his house and filling the gasbag of his motor car without allowing the gas to pass through the meter.

Motoring to Weddings.

Although the use of motors by wedding parties is definitely declared by the latest Order to be illegal, a case of this nature has been dismissed by an Irish magistrate. His argument was that at the present time nothing was more important than weddings and christenings, and that, con-uently, the wedding would be regarded a necessary household affair and the e dismissed.

e Annual General Meeting of the Motor Cycling Club.

The year 1917 was an uneventful one or the Motor Cycling Club. Owing to the continuance of the war the club was forced to remain inactive, and as the members have been exempted from paying their annual subscription the revenue has been dependent upon interest on War Loan. As may be imagined, the attendance at the annual general meeting was not large, only about a dozen members putting in an appearance. Among them were Vivian Olsson, formerly in the R.N.A.S., but invalided out owing to rheumatism, after a long spell Overseas; B. A. Hill, Sec.-Lt., R.F.C., who was the proud wearer of the Mons ribbon; Harold Karslake, a warrant officer in the same corps; and E. Bridgman, an inspector in the Special Constabulary (H.Q.C.D.)

The proceedings of the meeting were purely formal. On the proposal of Mr. R. H. Head, chairman of the committee, Mr. E. M. P. Boileau *(The Motor Cycle)* was elected to take the chair at the meeting. The first item on the agenda was the reading of the notice concerning the meeting at "The Monico," Piccadilly, London, W.1, at 6.30 p.m. on Wednesday, January 30th. The minutes of the last annual general meeting were then read and confirmed, and next the report and accounts were duly received and adopted. The only matter in the report, on which a question was raised by Mr. B. Marians, was the reference to the fact that a considerable number of unclaimed awards remained in the hands of the club.

The next procedure was to elect officers, the committee, and an auditor for 1918. Those who served during the past year were duly re-elected, and are the following: President, Maj. Charles Jarrott, O.B.E., R.F.C.; committee, Messrs. R. H. Head (chairman), A. Candler, A. C. Armstrong, E. Gwynne, P. G. E. James, H. G. Bell, H. Karslake, B. Marians, R. B. Clark, C. J. Seed, E. Bridgman, and H. F. Edwards; captain, Mr. W. H. Wells; secretary *(pro tem.)*, Mr. A. Millbourn; and auditor, Mr. W. Richards.

The meeting terminated with a vote of thanks to the chairman.

Unclaimed Medals.

Numerous unclaimed gold and silver medals and other awards are in the possession of the Motor Cycling Club. All who have not received the awards they earned in 1914 are requested to communicate with the secretary, Mr. Arthur Millbourn, 19, Baker Street, London, W.1. All clubs and individuals who are holders of perpetual cups or trophies are asked to return them as soon as possible to Mr. Millbourn.

It appears that all members have been asked to claim their awards, but in many cases no replies have been received. It is obvious that the Club cannot undertake to post them to those members who have won them, as so many addresses must necessarily have changed in the period which has elapsed.

Accumulator Supply for Electric Lamps.

A motor cyclist in the Letchworth district was recently summoned for riding without a light. According to the *Letchworth Citizen*, it was stated on behalf of the defendants that "the water in the accumulator was frozen, and that the defendant could not get the required amount of gas for the acetylene lamps." A correspondent—"Kuklos"—writes to us: "I wonder if there was enough carbide in the magneto to make the plugs spark."

Wholesale Motoring Restrictions.

The following paragraphs from *The Autocar* of January 26th give some idea of the restrictions on motoring now existing in all parts of Europe. This information may make even those agitators against English restrictions pause to think a trifle:

IN FRANCE.

"Under the new system of taxation in France a tax of 10% is imposed on purchase of luxuries, including motor vehicles, so that a £500 car will cost £550."

IN SPAIN.

"Owing to the serious petrol shortage in Spain the Government has ordered all gas and coke-making establishments in the country immediately to take every possible step to increase the output of benzole."

IN NORWAY.

"In Norway the use of private cars is forbidden, only vehicles on work of a national or public character being allowed."

IN GERMANY.

"The Germans are using alcohol obtained by distillation of the residual liquors of cellulose factories as motor spirit."

IN THE NEW DEMOCRACY.

"Petrograd has imposed a new tax on motor cars of 150 roubles (about £15) per horse-power."

IN HOLLAND.

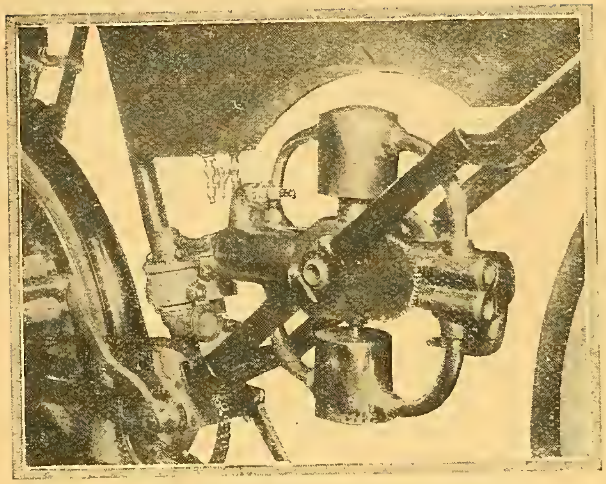
"For six months no petrol has been imported into Holland from America. The scarcity began when a tanker with 2,000,000 gallons was torpedoed off Ymuiden, and since then all petrol has gone to the military authorities.

An Indian sidecar used by a sportsman in America to carry his "bag," which in this instance consists of a fine buck. The animal was brought down about ten miles from the Springfield factory where the Indian motor cycles are made. In these famine days many British motor cyclists would like to be using their outfits for a similar purpose.

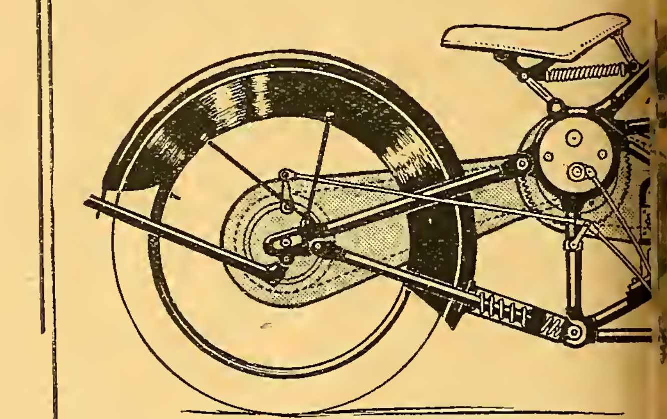
("*Motor Cycle and Bicycle Illustrated*," *New York*.)

ROTARY & RA

A RÉSUMÉ OF PAST AND PRESENT EFFORT AT
AND DESIGNING THIS TYPE OF ENGINE FOR MOTOR



The Barry two-cylinder opposed rotary engine adapted to a motor cycle in 1904. The silencers are balanced and opposed, rotating with the engine. The cylinders are offset, the crank being double throw, set at 180°, thus giving even firing.

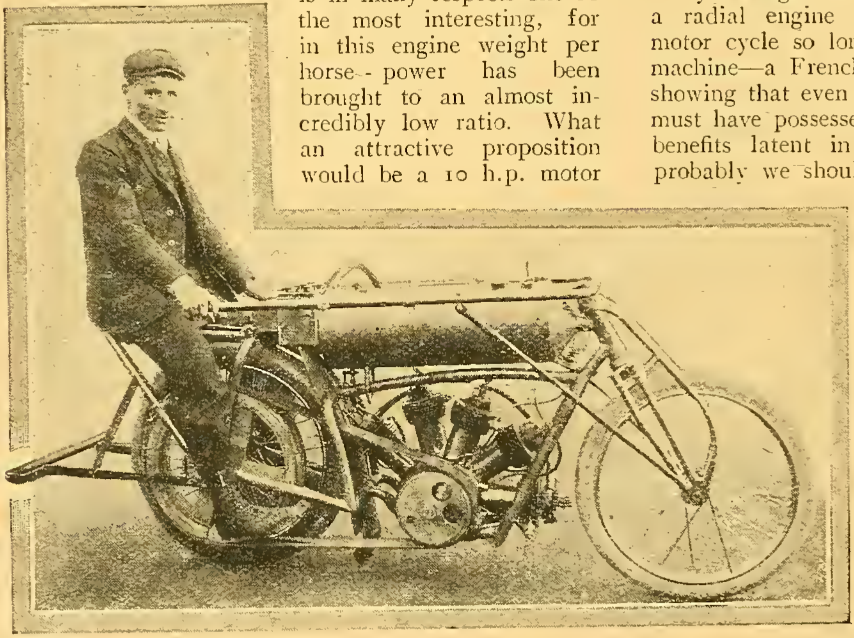


The unconventionally designed machine described in the acc
is the fitting of the rotary engine, the carburetter of which is
rear springing arrangement will doubtless cause some criticism a
consideration of our readers. The sketch was sent by M. Henr

THERE is at the present time a great deal of talk on the question of adapting rotary and radial engines to motor cycles. The remarkable developments that have taken place in rotary, and, indeed, in all types of engines used in aeroplanes, have produced in the minds of motor cycle engineers new ideas and aspirations—ideas, too, that may be termed revolutionary when the rather stereotyped designs of motor cycle engines in general use are borne in mind. That the war has given a great impetus to the designing of light but powerful engines for motor cycles there is no doubt, and without question after the war the great progress made in aero engine manufacture will be reflected on the motor cycle industry.

Of the numerous types of aero engines, the radial is in many respects one of the most interesting, for in this engine weight per horse-power has been brought to an almost incredibly low ratio. What an attractive proposition would be a 10 h.p. motor cycle weighing about the same as a T.T. model. Yet, in spite of the scoffers, this may come about, and the use of a radial or rotary engine may enable it to be done. Of course, there are numerous points that would have to be carefully considered before these types could be rendered suitable for motor cycles, but the experiments that are taking place go to show that many clever engineers see a great future for them. It is interesting to look back and to find that *The Motor Cycle* was alive to the possibilities in this type of engine over ten years ago, and it is certainly remarkable that a radial engine should have been built into a motor cycle so long ago as twenty years. This machine—a French production—ran successfully, showing that even at that early date the designer must have possessed remarkable insight as to the benefits latent in this particular design. And probably we should not be far wrong in stating that this was the first radial with more than three cylinders to be successfully made. Now, two decades afterwards, we see radials and rotaries developed to an extent not dreamed of even seven years ago, and taking a place in aeroplane work which no other engine is likely to usurp.

Then there was the Barry of 1904—a rotary engine shown at the Stanley Show. Few were the motor cycling enthusiasts who refrained from sarcastic remarks on first beholding this engine of revolutionary design—a type many years before its time.



A 20 h.p. five-cylinder Esnault-Pelterie fitted to a racing motor cycle in 1908, and at the time the lightest engine for its power yet constructed for a motor cycle.

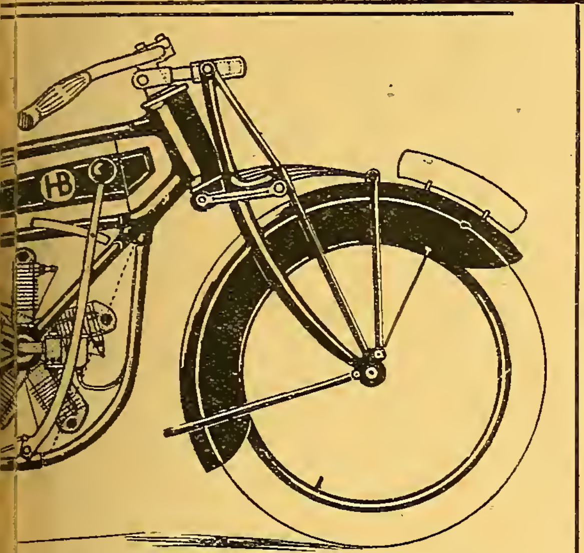
AL ENGINES.

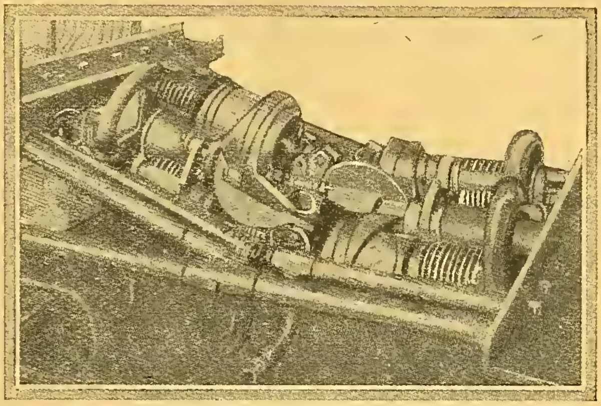


The system of frame springing is as worthy of note as projecting forward from the centre. The working of the as to how it works, and we commend the problem to the lench reader.

They failed entirely to appreciate the object the designer had in view, *i.e.*, the production of an engine giving considerable power with little weight, and also smooth running. The machine was extremely nice to drive, very flexible, free from vibration, and not prone to overheat—attributes which one thinks would surely have led designers to further experiments in that field.

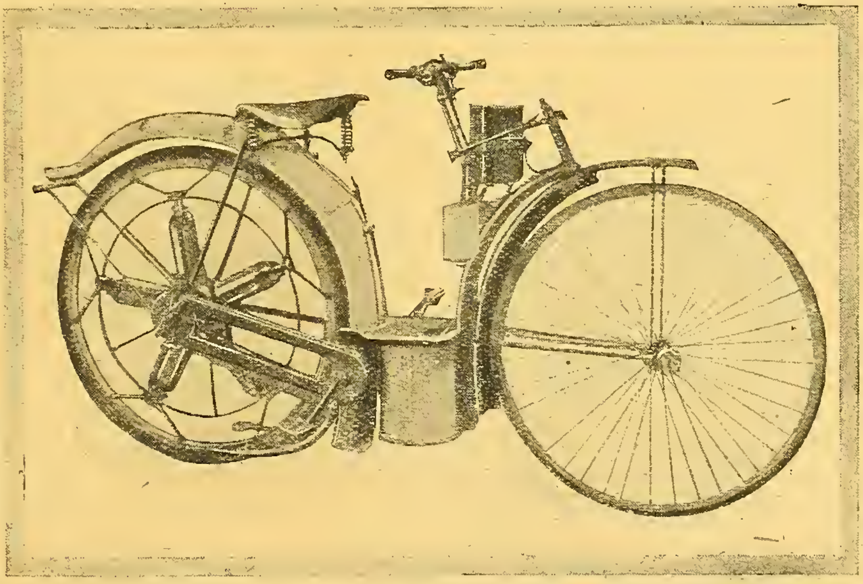
In spite of the unquestionable success of radial and rotary engines on aeroplanes, it does not follow that this type will be easily adapted to motor cycles. There are many features about it which, at present, would be very objectionable in a motor cycle, but which matter very little to an airman. Comparatively speaking, the life of a rotary engine is short and consumption of oil and petrol great. These drawbacks, however, may be gradually overcome when the proposition of fitting them into motor cycles is tackled seriously. It must be remembered also that an aero engine is required to run continuously at practically full power, and cannot fairly be compared with the motor cycle engine, which is rarely called upon to develop its maximum output.

Other types of radial and rotary engines which we have from time to time described are reproduced once more.



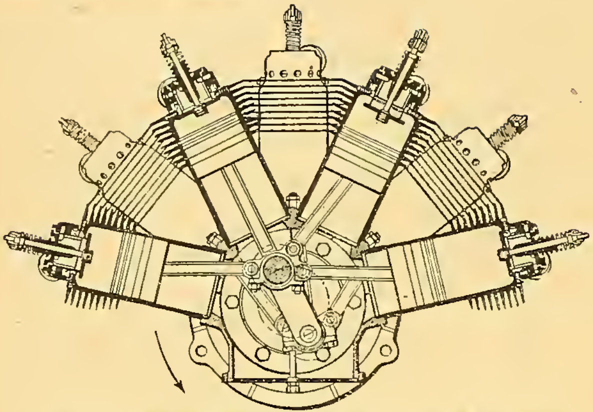
The A.R. two-stroke rotary engine. An unconventional design described in December, 1913, consisting of two pairs of cylinders mounted on independent shafts connected by a universal joint. The lower portion of the cylinders acted as the compression chambers. After the gas was compressed in one cylinder it descended through the transfer ports to the combustion chamber of the cylinder beneath it.

The Anzani engine, which was probably the earliest practicable radial purposely designed for aeroplane work, is shown. The fan-shaped engine was the first manufactured, and some time afterwards the Y pattern was evolved. Some of the radial and rotary engines shown are ingenious in design if rather impracticable. The A.R. two-stroke, for instance, shows great originality, and in it there is the nucleus for an engine of startling design. This brief review of former efforts shows, however, that many designers have in the past realised the possibilities of this type of engine, although their endeavours at the time were not directed to the obtaining of great power in proportion to the weight of the engine, as would be the chief aim to-day.

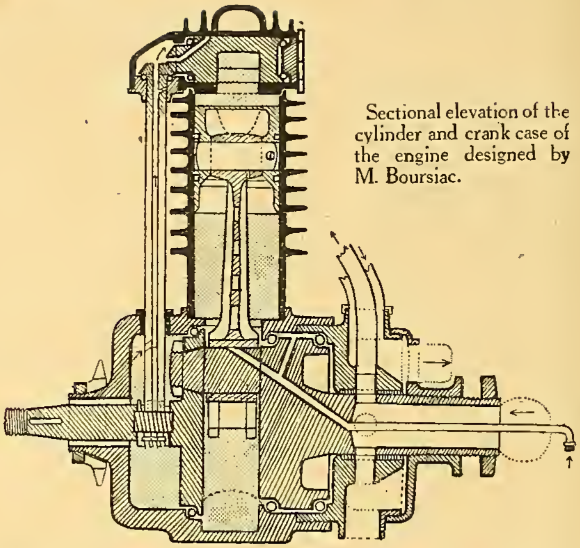


A rotary engined motor cycle, built in France in 1896, and probably the first rotary ever built. It will be observed that the engine has five cylinders and is located in the rear wheel. The general design of the machine is extraordinary, but it would be a relic worth possessing.

Rotary and Radial Engines.—



The 30 h.p. Esnault-Pelterie engine, described in full in January, 1908. The seven cylinders are divided into two groups, one of four and the other of three cylinders, and assembled on one crank chamber. Each group has a separate carburetter, all the combined inlet and exhaust valves being operated by one cam wheel.

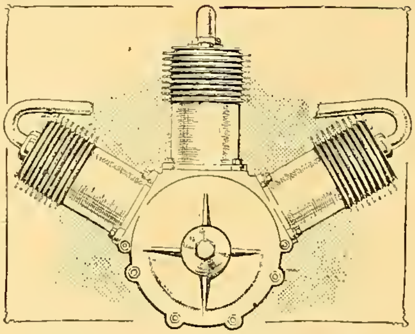


Sectional elevation of the cylinder and crank case of the engine designed by M. Boursiac.

The latest motor cycle design, both of a rotary engine and of a special frame to hold it, has come quite recently from M. Boursiac, a French rider.

A French Rider's Idea.

It will be observed that the three members supporting the engine are of duplex construction, so that the stresses are equally distributed both laterally and vertically, thus making the crankshaft the centre of a perfectly triangulated structure. The transmission from the engine to the rear wheel is through a countershaft gear box, which is placed immediately underneath the saddle, the drive from the engine to the countershaft and from the countershaft to the back wheel being by chains. The clutch lever will be seen on the right of the tank, and is of the Indian type. The change speed gear lever is invisible in the drawing, and the type of gear box is not made clear by the designer i his letter to us.



Sectional view of the fan type three-cylinder engine, the earliest type produced by Anzani. In 1914 Messrs. Anzani were producing twenty-cylinder rotary engines of 200 h.p.

The springing of the frame i particular interest, and it wil noticed that the front spring f are very much on the lines descr in the Sunbeam patent in T *Motor Cycle* of November 22nd, but there is no suspicion or possibility that the French idea is in any way a copy; also, the handle-bar is adjustable for height on lines similar to that

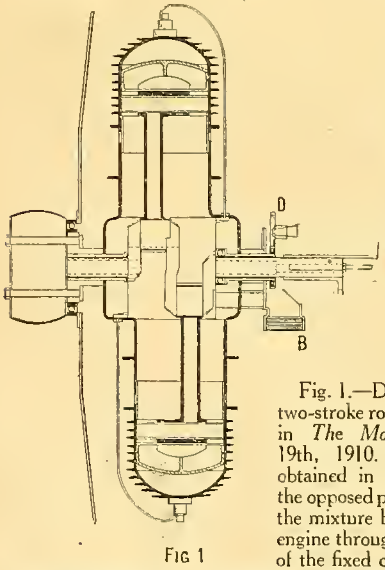


FIG 1

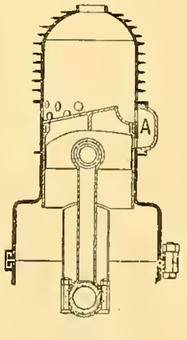

FIG 2

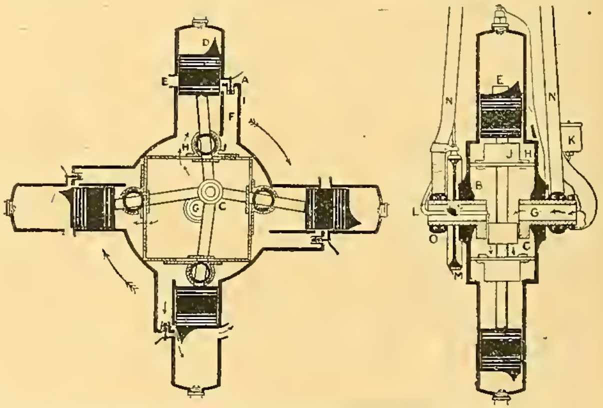
Fig. 1.—Diagram of the Farcot two-stroke rotary engine described in *The Motor Cycle* of May 19th, 1910. Compression was obtained in the crank case when the opposed pistons came together, the mixture being drawn into the engine through the hollow portion of the fixed crankshaft. A shows fixed distributer, B attachment for carburetter. Fig. 2 shows cylinder, piston, and crank case of the engine.



A four-cylinder two-stroke rotary engine designed by E. Dobson, and published by us in November, 1911. The sketch shows the engine with slide valves operated by the connecting rods. The advantage claimed for this was that it would dispense with crank case compression, and measure the correct quantity of gas for displacement of the exhaust.

A. Air scavenging valve

O. Ball bearings, enabling crankshaft to rotate when brake is released

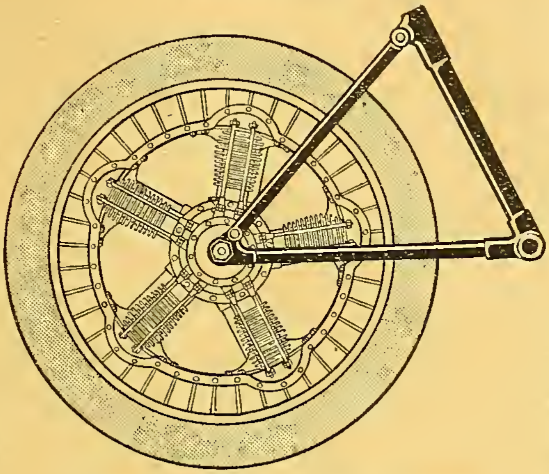
Rotary and Radial Engines.— described in *The Motor Cycle* of December 13th.

The springing of the rear portion of the frame may be clearly seen in the drawing to consist of a hollow rear lower tube (or chain stay) in the front portion of which is a spring working in compression and resisting road impacts against a sliding piston to which the end of the tube pivoted at the wheel is attached.

The Engine.

As regards the engine itself, the designer has kindly sent us two detailed illustrations. It will be seen that the engine is of the rotary type with hollow crankshaft, and that the inlet is introduced through the hollow crankshaft, and is exhaust-jacketed, so that the incoming gases are adequately heated before reaching the cylinders. The bore and stroke suggested for this engine are 40 × 50 mm. The intention is to employ rotary valves.

Other points of interest in this extremely ingenious machine are the provision of adjustable footrests, as well as adjustable handle-bars, grip control — after American practice — the fitting of 28in. × $2\frac{1}{2}$in. tyres, enclosed chains, and internal expanding brake.

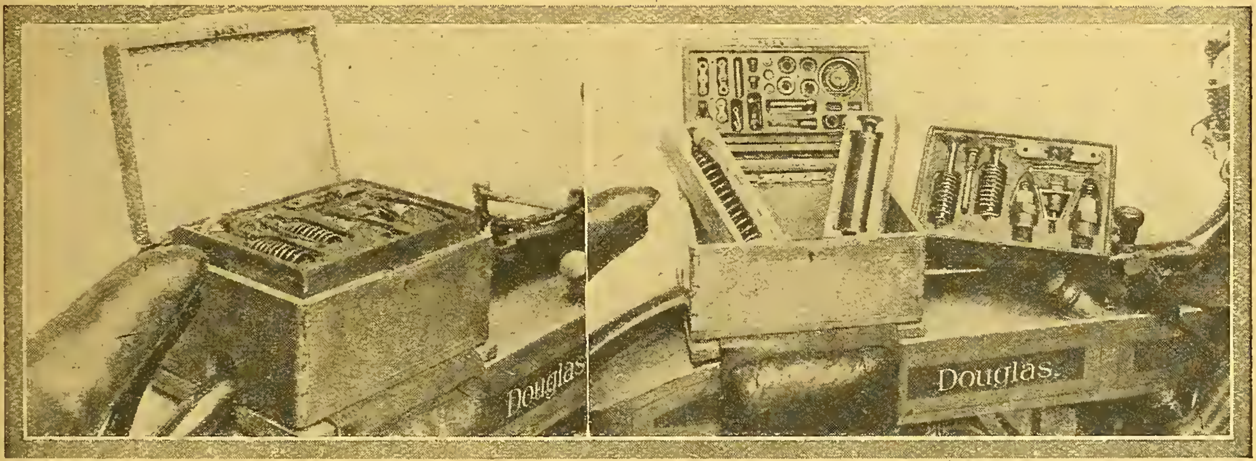


A Belgian design for a five-cylinder rotary engine submitted to us in March, 1916.

HOW TO CARRY SPARES.

A Device which in the Long Run will Save Time and Temper.

THE problem of carrying spare parts has often puzzled riders of motor bicycles. Many carry their odds and ends loosely in the toolbag, or merely wrap them round with rag, with the result that the parts often get damaged, or are carried in a more or less confused mass. Some people wire nuts and split pins together. This again is not a wholly satisfactory method, while anyone who has attempted to carry small parts, such as bolts, nuts, and split pins, more or less loosely in a tin box, knows that eventually the corners of the nuts become rounded and worn, and the parts ultimately suffer damage through the chafing caused by vibration.



An admirably contrived spare part carrying case fitted to a Douglas. The owner is to be congratulated on devising so convenient an arrangement Only too often are spare parts and tools rolled up in a jumble of dirty rags and carried loosely in the tool case.

The rider of the $2\frac{3}{4}$ h.p. Douglas whose system of carrying parts we illustrate has tackled the problem in a sensible manner. It will be noted that a well-made dovetailed wooden box is carried on the top tube, and in it each individual part has its own receptacle carved for it. The top tray carries two spare valves, a spare tappet, a belt fastener, a belt punch, and two spare plugs, each neatly recessed into its own partition so that damage is quite impossible. The second tray holds spare chain links, each link having a separate compartment, and the same remarks apply to bolts, washers, and even split pins. It will also be noticed that special carriers have been carved to take the grease gun and spare fork spring.

Such care meets with its own reward, as, when the rider desires to replace anything on the road, he may be sure that it can be quickly found, will be absolutely undamaged, and consequently quite ready for use.

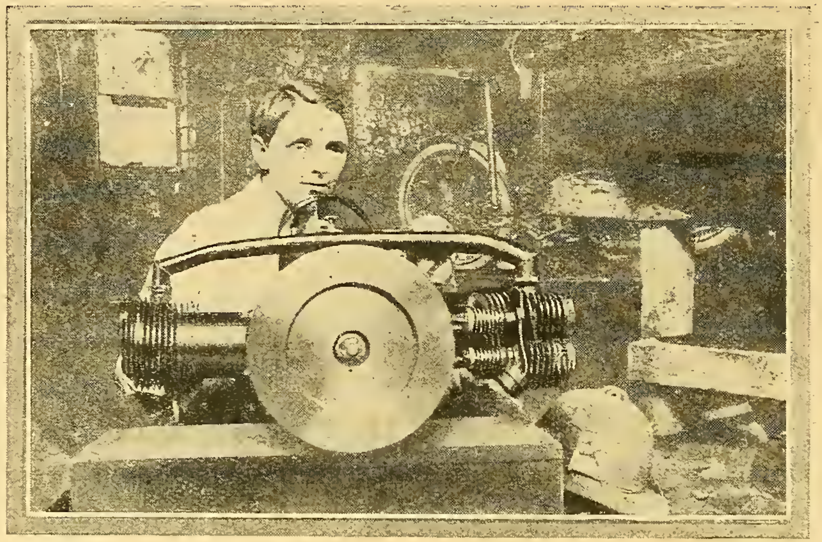
GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

A FLAT TWIN WITH TRIUMPH CYLINDERS.

Building up a Flat Twin Engine from Old Triumph Parts and other Discarded Scrap from the Machine Shops at Dar-es-Salaam, East Africa.

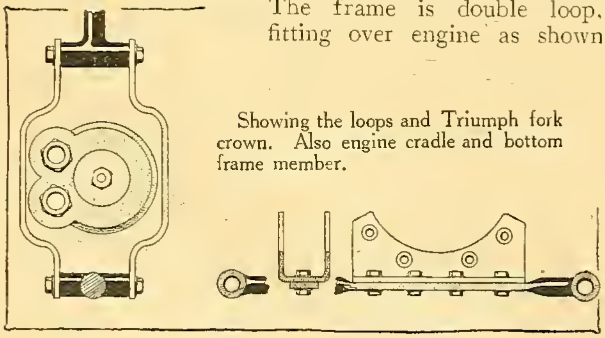


Sgt. Douglas Mail with the engine he built up in one of the Dar-es-Salaam machine shops.

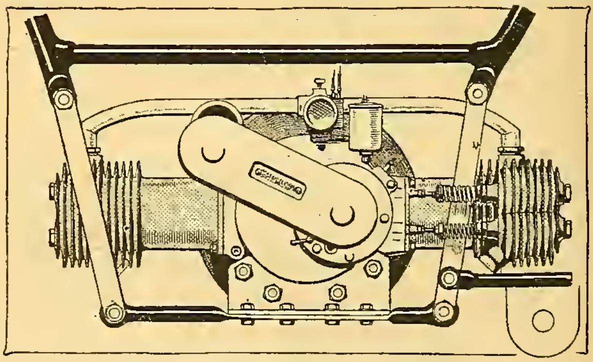
FROM Dar-es-Salaam, East Africa, Douglas Mail (Sgt.-Mechanic) sends the following interesting letter, together with a batch of photographs, reproduced on page 122, and also a description of a novel flat twin engine which he has with much skill and ingenuity built up from oddments. Although crudely finished, it strikes us as being good work, considering the limited means that were at his disposal, and it proves how keen and unabated is the interest in motor cycles, even in this outlandish place on the East Coast of Africa:

"I am sending with this description a set of photographs of various points of interest taken during the campaign. Though all are not actually connected with motor cycling, they may prove of interest.

"I have been experimenting with a big flat twin, which I have built of scrap Triumph parts, and send a photograph of this with myself in the background. At present I have it on test, and have obtained excellent results. Roughly the features are: Built-up three-piece crankshaft, with three bearings, two ball and one phosphor, in timing case cover. Of course, the engine is crude in some respects, owing to the conditions under which it was built. The cylinders being alike, two sets of valve gear were necessary, one on either side. A new set of cams I made for the near side, owing to their rotating in the reverse direction. One half-time wheel is a fixture on shaft, being brazed on, the main shaft bearing recess being skimmed out to allow it to pass through. The frame is double loop, fitting over engine as shown in the sketch. Note that the gear box shaft is longer than usual, to allow for chain alignment. The engine throttles down well, gives very slow running, and has exceptionally rapid acceleration. As an experiment it is, I think, rather unique. I am not aware of another one being built on the field. And it would be interesting to learn if any other engine has been built from what was practically improvised material. All the boys here were anxious to see how my experiment panned out. I think of making several improvements, the results of which are likely to be even better than those obtained up to the present.



Showing the loops and Triumph fork crown. Also engine cradle and bottom frame member.



The 8 h.p. flat twin built up from two Triumph cylinders and other oddments.

The range of experiments I have the intention to make, if they can possibly be carried out, will be in my next letter. But unfortunately we never know when or how suddenly we may be removed."

According to a preliminary estimate by the Geological Survey, the amount of petroleum produced and marketed in the United States last year reached the record-breaking total of 341,800,000 barrels. The quantity exceeded by 14% the record output of 1916. The enormous demand absorbed not only the current output, but necessitated a draft of about 21,000,000 barrels of the oil in stock, principally in California and Illinois. The surface reserve of crude oil at the end of the year is estimated at 153,000,000 barrels.

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

FUEL LOSS AT CARBURETTER.

Sir,—Surely your contributor "Engro," in January 24th issue, is wrong in his calculation of gas velocity on suction stroke. 1,200 r.p.m. = 20 r.p.s.—the suction stroke, therefore, which is, roughly, half a revolution, is completed in one-fortieth of a second, in which time twenty cubic inches are inducted. $\frac{20\times40}{.7854} = 1{,}018$ inches per second velocity—a comparatively low speed, yet four times his figure.

J. W. G. BROOKER.

POST-WAR DESIGN.

Sir,—I have followed very closely the correspondence on post-war designs in *The Motor Cycle.* In your publication of September 27th, 1917, which I have just received —rather late, but still most acceptable—my interest was aroused by the suggestion of Wallace R. Warne *re* the Knight engine for motor cycles.

As anyone who has had practical experience with cars will know, the Knight engine has all the qualities "W.R.W." describes, and I think they should be very successful on motor cycles. But why use a double-sleeve valve engine when a single-sleeve Argyll engine is so successful? This engine having only one sleeve has less friction, and therefore generates less heat. It should also be very much lighter with the absence of one sleeve and two eccentric shafts. To replace the shafts it has a worm-driven eccentric pin. Excepting the design of the piston it has all the other qualities stated. I quite agree with "W.R.W." on all his other points, and I should very much like to own a perfectly silent model. Good luck to the "Blue 'Un."

M.E.F. ARREMMA.

TECHNICAL INACCURACY.

Sir,—I have been closely following the absurd letters (on both sides) on "Technical Inaccuracy." It really seems impossible that people can be so childish as to "squabble" over a story which was obviously intended to be humorous, and the only explanation I can think of is a longing to see their names in print! Had "A Race with Ruin" been put into *Punch* these *precise* readers would have laughed at it. May I refer to a story in *Punch's* Almanack for 1918, entitled "George's V.C."? Why did no Army people write against the many absurd jokes in that? For instance, does a colonel postpone an important interview because a sergeant-major would like to speak to him? No; of course not; but it was just a joke, a good humorous story, and everyone knew it. So here, "A Race with Ruin" is a humorous story, and not intended to be correct in details; that is half the fun of the story!

With regard to the letters of Chas. S. Ives, F. Jones, and "R.O.W.," surely the writers have more decency than to "stick up for" the murderers of Nurse Cavell and Capt. Fryatt, the sinkers of the *Lusitania,* and the instigators and executors of hundreds of other crimes. I entirely agree with Sec.-Lt. Addenbrooke that if you begin to run short of readers some of us will have to take several copies per week.

Glasgow. A.R.C.H.

PISTON DESIGN IN TWO-STROKES.

Sir,—I received *The Motor Cycle* of January 17th, and note Mr. Martin's reply to my letter.

I quite agree with his statement that a small amount of vacuum is caused in the cylinder owing to the inertia of the exhaust gases passing out of the exhaust port: otherwise, with the comparatively low crank case compression employed on most two-stroke engines, it would be impossible to transfer a sufficient volume of gas, *via* the transfer port, to obtain efficient running.

I still maintain that, with the rings situated at the bottom of the piston (as shown in Mr. Martin's fig. 4), a certain amount of compression would be lost before the piston reached a point in the compression stroke where the rings shut off the part of the cylinder above the piston from the ports.

It would be an interesting experiment to fit a standard two-stroke engine with a piston of Mr. Martin's design and of the same weight as the original standard piston and note the results obtained with each type in the same engine.

D. J. McDOUGALL.

AMERICAN AND BRITISH MACHINES.

Sir,—In your issue of January 24th I notice that "Chinook," speaking of the twist grip control system, says, "In traffic, for instance . . one's natural impulse on seeing an opening is to give the twist grip half a turn, thus banging the throttle open," etc.; but, as a constant user of this type of control before the war, I am quite unable to perceive any reason for this statement. Further on he also says, "The twist grip throttle control has three positions in ordinary use—pilot, half throttle, and full throttle—no other stages being recognised by the rider," but surely this is open to discussion.

Personally, I find that the great advantage of the American system is that it permits one to retain a strong grip on the controls *at all times,* whereas with the lever controls it is necessary to release one or more fingers from time to time, which is quite a big disadvantage on very rough roads. In spite of this, I have nothing but praise for the Triumph, which is undoubtedly "the goods" for active service.

I should like to add that I have enjoyed many articles by "Chinook," and am a constant reader of the "Blue 'Un," which reaches me every week. CANADIAN D.R.

B.E.F., France.

LUBRICATION IN INTERNAL COMBUSTION ENGINES.

Sir,—I notice in your issue of January 24th a statement is made in an article on lubrication that steam engine cylinders which have been running for years are to-day in as good condition as on the day of their erection, but that such reduction of wear is impossible with the internal combustion engine. Further sentences state that the bearings of the internal combustion engine have a comparatively short life.

These statements appear to me to be exaggerated. There are plenty of internal combustion engines which have worked steadily for ten to fifteen years or more and are still in perfectly good condition. I know one which was running perfectly after seventeen years' continuous work, during which the main bearings had never been adjusted, and the big ends only once. Such engines, in fact, are often scrapped when in perfectly good condition because the owner wisely prefers to get a more modern type of engine.

On the other hand, certain types of steam engines require pretty frequent adjustment, and some have the cylinders cast a good deal thicker than necessary for strength to allow for frequent reboring.

If the internal combustion engines used in motor vehicles do not wear as those I have mentioned it is simply because long wear is sacrificed to other considerations.

F. STRICKLAND.

WIRING AN ACCUMULATOR LIGHTING SET.

Sir,—"Chinook" unfortunately omitted to give the consumption of the small lamps, but if we assume them to be 0.5 ampère lamps, and connected in series, we get

$$\frac{4 \text{ volts}}{8 \text{ ohms} + 8 \text{ ohms}} = 0.25 \text{ ampère passing in the circuit,}$$

sufficient to heat the filaments to a red heat.

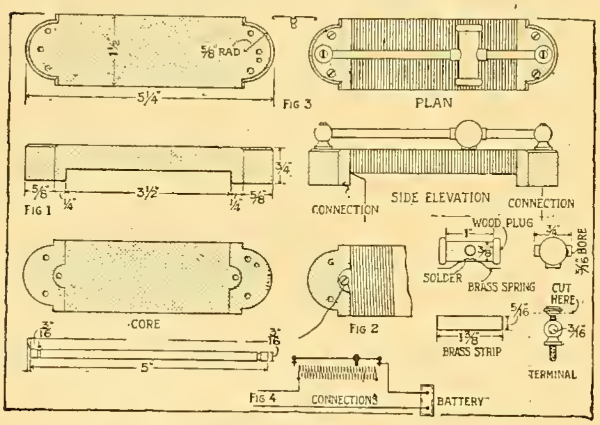
With the addition of the head lamp in series we get

$$\frac{4 \text{ volts}}{16 \text{ ohms} + 4 \text{ ohms}} = 0.2 \text{ amp. passing a current quite useless}$$

for the purpose required.

It will be seen from the above that three lamps made to consume 2 amps. altogether can hardly give any light with only 0.2 amp. passing. If "Chinook" is satisfied with the light in the side and tail lamps he can easily regulate the current in the head lamp by inserting a small sliding rheostat in series with the wire leading from the battery to the head lamp. Another plan would be to fit 4 volt 0.3 amp. lamps in the side and tail lamps connected in parallel with the rheostat inserted between the switch and the earth point.

With this plan all three lamps can be regulated simultaneously. With the lamps in parallel more current will be used (1.6 amp. against 1.25 amp.) when the lamps are burning at full pressure. A rheostat is an extremely useful instrument to have with any accumulator, as it not only protects the battery but increases the life of the lamps.



The cheap and simple electric rheostat here described.

The materials required are a piece of hard wood 5¼in. × 1½in. × ¾in., two ball-shaped terminals, a piece of brass rod 5in. × 3/16in., two pieces of brass tube 1in. × ⅜in. and ¾in. × 3/16in. bore, a piece of brass strip 1⅜in × 5/16in., seven yards Eureka wire No. 20 S.W.G., four 1in. screw nails, and two ⅜in. screw nails, the screws to have half-round heads. Take the wood core and cut to the shape shown in fig. 1. Place a footrule ⅞in. from one end, and mark off every 1/16in. for a distance of 3½in. Then take a T square and a sharp pencil and run lines across the top and down the sides. Then turn the core over and continue the lines on the under side in the way shown in fig. 2. A shallow groove must now be formed over the line previously marked. The groove should be sufficiently deep to hold the Eureka wire in position (about half the depth of the wire would do). The core can now be coated with shellac varnish and the ends blackened and polished. Fit the two small screws in the holes on the under side of the core, then take the Eureka wire and a short length of copper wire and twist the ends round one of the screws on the core, then proceed to wind the resistance wire tightly round the core, finishing at the screw at the opposite end.

The details of sliding spring, etc., are clearly shown on the drawings, and hardly require any description.

Fig. 3 shows a plan and side elevation of the rheostat completed, and fig. 4 the connections.

It will be seen at a glance that by moving the sliding spring a longer or shorter piece of resistance wire is inserted, thus controlling the strength of the current. The most convenient place for the rheostat is on the battery box in a horizontal position.

A. A. MORRISON.

GOODS MADE IN GERMANY!

Sir,—May I, as a constant reader and one who regularly looks for a copy of your excellent paper arriving from Blighty, express an opinion? When I first saw your advertisement *re* German goods my first impression was: Well, this is an all-British paper anyway.

On reading an expression of opinion by C. S. Ives it simply raised my contempt and passed from my mind. But now, on receiving the January 3rd edition, I find that opinion endorsed by others. It makes me disgusted to think there are (there cannot be many) Englishmen who formulate such ideas, and then put them in the category of sport.

One, "R.O.W.," mentions the Bosch magneto as the developer of the petrol motor. I contend it simply held back the advancement of British goods, inasmuch as it flooded the British market at a cheaper rate and worked. Hence the trusting British public found no reason to manufacture a like article. What about the British magnetos of to-day? Are not they efficient?- They could have been made years ago if needed.

We are fighting against our own money now, which was paid for those magnetos, among a colossal number of other things. But, there, one need not go into that part of it; it is *business* more than politics.

We have threshed it out in this ward (I am in hospital at present), and have come to the unanimous conclusion that such sentiments are tainted with Boloism and decidedly pro-German.

A NEW ZEALANDER.

France.

Sir,—An old adage says, "Even a worm will turn," but after reading the effusions of Mr. C. S. Ives, etc., in recent issues of "our" paper, one can only wonder *what would* cause these "worms" to turn.

One blushes to think that these white-livered gentry call themselves "Britishers," as no doubt they do. What *could* the "German beast" do more than he has done to make the world realise that "the only good German is a dead German"? The horrible crimes against humanity, civilisation, and common decency, that are a deliberate part of German policy, and are approved and applauded by the German people, do not stir the blood (?) of these "patriots" of the C. S. Ives type one iota!

They utter no protest against Hunnish devilry—no words, even, of sympathy with the victims, even when they are their own fellow-countrymen and women. Their sufferings at the hands of the loathsome Huns leave them unmoved. But at the least suggestion of just retaliation, even to the mild extent of refusing to shake the hand of the "blonde beast" (as they love to call themselves), still dripping with the blood of outraged, tortured, and murdered women and children, these "worms" writhe in agony!

The mere suggestion that we should refuse to take to our bosoms these enemies of the human race—these "vermin of civilisation"—still gloating over and glorying in their unspeakable crimes, gives Mr. Ives and his friends most exquisite pain! Can one wonder that as one contemplates these specimens of British (?) manhood one experiences a feeling of nausea? Pah! an ounce of civit, good apothecary!

You, sir, will have the approval and support of every Britisher worthy the name in the manly and patriotic attitude you have adopted in having "no truck," either now or in the future, with the "German beast."

GEO. P. WADDINGTON.

Sir,—When I first read your notice I greatly admired your idea, and was very much surprised at reading the letter of Mr. C. S. Ives. I was disgusted to think that anyone should ever write such pro-German rot, and yet have the cheek to want to dictate to you on what lines you were to conduct your paper, or to think that the withdrawal of his support would make you "put your shutters up." If some of your pro-German correspondents had stood under a Zepp. in an air raid, or been torpedoed and turned adrift on a raft hundreds of miles from land, without food, at night this winter, it might alter their views, and probably they would not be so keen of spending their money in Germany or yet have much love for the Huns.

I have been a motor cyclist for fifteen years, and a regular reader of your paper, and I was disgusted to think that there are supporters of Mr. Ives's views amongst your readers. To think that one of your correspondents should say, "Let us show we have no quarrel with the Germans."

What rot! What disrespect for the boys in blue and khaki who have kept the German devils from making our homes and families like they made the Belgians'. Have not these pro-Germans ever heard of Nurse Cavell, Captain Fryatt, the *Lusitania*, and thousands of other brutal outrages too numerous to mention? And then to find there are people living in England to-day childish enough to withdraw their support from your paper because you refuse to advertise German goods. How rotten!

Would "R.O.W." have us forget all the millions of brave lives and millions and millions of money and thousands of cripples, and all the gallant motor cyclists who have become pilots in the R.F.C. and fallen in battle, and forgive, all because the Germans put the Bosch magneto on the market? If so, it is too foolish for words.

I wish your paper the best of luck, and hope you will stick to your guns and let Mr. Ives and his supporters withdraw their patronage and buy German goods. For my part, I shall never buy another German article of any kind, but support home industries and buy English motor cycles with all English parts, and support the workers that have fought for dear old England.

ROBERT S. TURNBULL.

FLYING FACTS AND THEORIES.

Sir,—I must thank "A Pilot" for his "hints to the young," but regret that he has misconstrued my second letter. This, I admit, bore little relation to my first, and was chiefly concerned with taking several remarks of Mr. Aston's very literally in order to find out whether or not they were so intended.

I have never directly stated, nor meant to infer, that an aeroplane needed no more power to sustain it on a turn than in straight flight, as this is almost an axiom. Incidentally, my letter was not written in anger or even sorrow.

With regard to Mr. Aston's contribution, as I have admitted above, I took his sentences literally, but I submit that I was not entirely unjustified in doing so, taking into consideration the remarks contained in the last paragraph of his article.

By "feel of the machine" I mean the feel of the controls, which tells anyone with experience when he is getting near stalling point; and also, if fit to be in the air alone, one can tell by feel whether one is banking correctly or not. Further, anyone who is any good at all flies by feel, and I am glad to say that the pretty little gibe contained in his (Mr. Aston's) last sentence falls entirely flat, and raises no reminiscent blush.

I would like to add that, when flying above clouds, one has a perfectly good cloud "horizon" to work with. Night flying and cloud flying are, of course, different, and frequently call for the use of instruments.

Mr. Aston further enquires how one is to know, when above clouds, which way the wind is blowing, and to this I would reply, "Compass."

Incidentally, anyone who read my letter carefully would have seen that I used the phrase "comic speedometers," etc., in connection with the cyclist only.

O.J.F.S.

Sir,—I remember hearing it stated that a nose-diving aeroplane cannot attain a speed of above 140 m.p.h. The reason given was that the air resistance at this speed balances the force of gravity, and that consequently further increase in speed is impossible.

If this be true—and I am not rashly asserting that it is not—can anyone explain how it is that a Bristol fighting plane is actually tested to dive at 260 m.p.h., and frequently performs this feat, the nominal limit being 300 m.p.h.?

A friend of mine recently dived at 160 m.p.h. in a RE 8, the result being a broken tail.

Surely if it is a question of air resistance, that resistance must depend on the size and type of machine, incidence of wings and tail, etc.

LOOT.

Ashton-under-Lyne.

ANOTHER LIGHTING PROBLEM.

Sir,—I wonder if one or two of the many readers who responded to "Chinook's" enquiry *re* electric lighting connections will be so good as to help me out of a similar difficulty. My problem is similar to "Chinook's," except that it is in connection with a solo mount.

(1.) How can I wire the set so as to obtain a good light from the front lamp, and just a glimmer from the rear lamp for ordinary running, while for leaving the machine in town at night-time I would like to have just a glimmer both front and rear?

(2.) What would be the most suitable accumulator to use in connection with, say, a 12 c.p. bulb in front?

(3.) What sort of bulb for the rear—candle-power and voltage?

(4.) What voltage would a 12 c.p. bulb require?

(5.) What make of bulb would be most suitable?

(6.) Where could I obtain the above accumulator and bulbs? I do not want a complete set like the Lucas.

R. PERCY.

FLYING IN A CURVED PATH.

Sir,—I note in your issue of January 17th a correspondent, "A.A.S." of Norwich, states that the rudder of an aeroplane is responsible for the loss of energy on turning.

The sketch represents an aeroplane about to turn. The rudder AB is deflected, and the air, after meeting it, is also deflected along AB. The air in being deflected causes a force to act on the rudder in direction CD, perpendicular to the plane of the rudder. The point is this, that no force acts on the rudder in direction AB, because the air is free to move in this direction. The only force which the rudder receives is a force along CD. It follows that the loss of energy is not in the rudder.

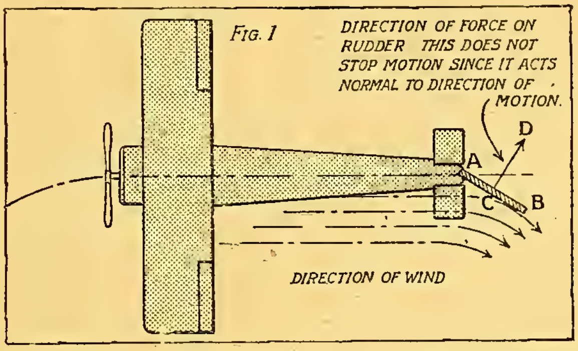


FIG. 1
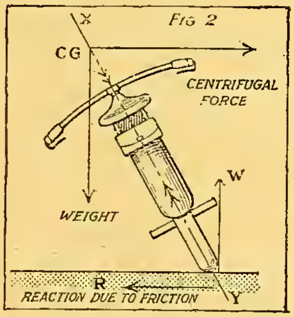
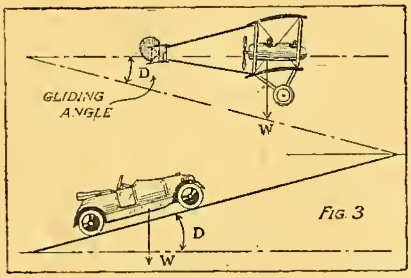
DIRECTION OF FORCE ON RUDDER THIS DOES NOT STOP MOTION SINCE IT ACTS NORMAL TO DIRECTION OF MOTION.
D
A
C
B
DIRECTION OF WIND



Mr. Walmsley's explanation, which appeared in the issue for January 10th, is the correct one. The present-day aeroplane, when flying horizontally at a certain uniform speed, requires more power than a motor car of the same weight and resistance would require when travelling similarly. Consider the aeroplane turning. The centrifugal force and the weight produce a resultant which is greater than the weight. Now this greater force has to be balanced; and although no potential energy is gained, more power from engine is necessary.



The motor cycle, on turning, experiences similar forces, and there is no doubt that, owing to extra load on the bearings, more friction is set up, and consequently some loss of energy. The forces are shown in fig. 2.

Our problem is to construct a machine which will travel through the air with as little disturbance as possible. The more the air is disturbed, the more the petrol energy is absorbed.

THOMAS LOWNDES SIMMS.

Boy Welfare in the B.S.A. Works.

Extracts from a Lecture given on the Subject at the Company's Works.

GREAT interest is being taken at the present time in the welfare work at factories, particularly in looking after the boys and girls, and the following extracts will be of interest as showing the enthusiasm of the B.S.A. Co. in this direction:

"Boys entering a factory were very largely neglected, both by their employers and by their parents. Neither gave sufficient consideration to their future careers," said Mr. W. L. Baylay, O.B.E., of the B.S.A. Co., who, in the course of an address given before the B.S.A. Staff Technical Club, stated that the B.S.A. Co. had prepared a scheme, which aimed at improving the life and training of the boys in the B.S.A. employ, and the speaker regarded it as a matter of duty to the boys, rather than as a commercial and philanthropic undertaking. The lads were divided into two sections, skilled and unskilled, and those in the former section would receive a special training in one of the skilled trades, subject to the parents agreeing to keep the boys in the firm's employment until twenty-one years of age. Classes would be held in the B.S.A. works during factory hours, and instruction given on general subjects, such as the writing of a simple report, elementary mathematics, and drawing, etc. To boys over seventeen years of age more technical subjects would be taught, suitable to the particular vocation each boy was intended to follow. The success of this special training was, of course, largely dependent on the selection of the most suitable boys, and for this purpose a gentleman had been appointed, who would take a personal interest in each boy, and would keep a history of the boy and his progress. These records would be of advantage to the best boys as a recommendation for their advancement, and an incentive to the other boys to strive for a higher standard.

Mr. Baylay explained that, though it was not at present possible to deal with the unskilled boys on similar lines, he felt that a great deal could be done by giving them something more to live for than only their work. With this purpose in view, a gymnasium has been equipped, where, under the supervision of a fully qualified instructor, they are taugh Swedish drill and gymnastics. The keen ness and delight of the boys attending these classes are very encouraging. Thes were not war measures. In Mr. Bayley' opinion the boys' welfare movement now being introduced into the B.S.A. work will in time be made compulsory in all factories. Not only will it result in healthier, happier boys, but will also give those boys who wish to progress a reasonable certainty that their effort will receive suitable recognition.

The gymnasium at the B.S.A. works, where boys employed by the company are taught physical drill. A résumé of a lecture given by the B.S.A. Co. on the welfare of boys and girls in factories is given on this page.

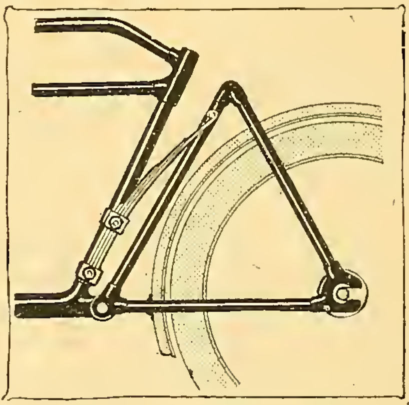
A Laminated Spring System for the Rear Wheel.

A Form of Springing which may be Adapted to Existing Machines with Slight Alteration.

THE employment of laminated springs and of a perfectly triangulated rear frame is the main point in the back wheel springing illustrated herewith. The design, which is by Pte. A. F. Markham, shows considerable ingenuity, and has several points not commonly embodied in such a system. Also, it could be fitted, with very little constructional alteration, to any existing machine of standard lines, and should involve a minimum of alteration to those small but important details that crop up when such an alteration comes to the point of being put into practice.

Removal of the Old Rear Frame.

It will be seen that the arrangement involves the removal of the old rear frame members, and the replacement of these by a specially constructed perfectly triangular rear frame, differing from the standard arrangement in the possession of a pivot at its forward apex and of a simple lug or bridge at the top, which is not provided with any means of receiving the saddle. This complete frame member is pivoted to the bottom bracket, as is the case in many of the new frame constructions, in such a way that it may revolve or give way when any shock is imparted to the road wheel. The amount of its movement is controlled by the action of a pair of laminated springs attached rigidly to the original down tube of the frame at some convenient point near the bottom bracket, one spring being on each side of the tube. The two tapered ends of these springs are attached to the movable frame member at the top extremities, *i.e.*, at their tapered ends.

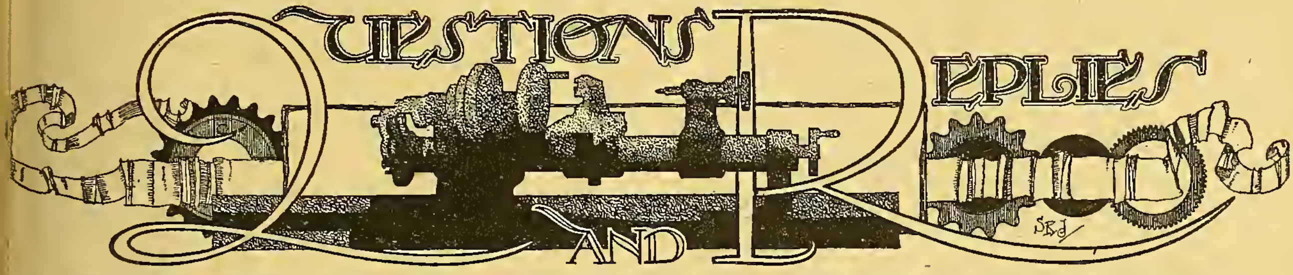


A rear springing system patented by Pte. A. F. Markham.

Reference to the sketch will make it clear that, should the wheel and its spindle receive a shock, the whole triangle of the movable frame will oscillate round the bottom bracket pivot, and that the extent of this movement will be naturally controlled and limited by the action of the two laminated springs.

A Simple Design.

The whole design seems very simple, and as it consists of a minimum number of moving parts it should have a claim to popular favour that is denied many of the latest spring frame designs. Also, we should be inclined to classify this design as one of the most easily adaptable to existing machines that has recently been brought to our notice.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Altering the Angle of a Magneto.

May I ask the favour of your advice *re* a matter which I am at a loss to work out for myself? I have a 5 h.p. V twin engine, the cylinders of which are set at 58°, and also a magneto (twin-cylinder type, 45°). Is it possible to convert the magneto to suit my engine, and if so, what is the best method?—S.W.H.

onverting the magneto would entail oving one of the steel cams on the con-ct breaker 6½° further retarded. We ould not advise you to attempt to do is yourself, but to get it carried out a firm of magneto experts.

Lubricating the Gear Box.

I shall be much obliged if you will tell me how often the grease in the gear box of a machine of the Baby James type requires renewal, also whether there is any method of removing the old grease, except through the plug at the top of the gear box. I should also like to know how long a good rubber belt is supposed to last with ordinary care. The one I have at present shows signs of cracking, *i.e.*, the rubber is cracked, but I suppose that this does not necessarily mean that the belt is done for, as otherwise it appears to be in good condition. —H.G.H.

he grease will last two or three ousand miles, but a little gear oil ay be added to it occasionally. The vel of the grease should not be higher an the bottom of the gearshafts. here should be a drain plug at the ottom of the gear box, and the grease n be removed by washing out with araffin. Your belt should last about 000 miles; your present belt is not ecessarily past work yet.

Repairing Bowden Cables.

Would you be good enough to tell me the correct method of repairing Bowden wires and the necessary tools required for doing the job? I have had great difficulty in getting these replaced, and intend to try to mend them myself in future.—H.W.

you mean by repairing that you wish splice the ends of two broken wires gether we can assure you that this is uite out of the question. The only pairing that can be done to inside ires is in the way of cutting off frayed nd broken ends and resoldering the nipples. Even then, if the strands are separated, the amateur solderer is apt to experience much difficulty. Replacing nipples is quite an easy matter. If the wire is too long it is first dipped in flux and then sweated—that is to say, solder is run over it with a hot soldering iron. It can then be cut without fear of fraying. The nipple, which should be quite clean, of course, is then slipped over and pushed on until about an eighth of an inch is protruding beyond the head. Then dip the nipple in flux and hold it in a flame, when the solder will run and make a good joint. The projecting ends may now be burred over and further secured by a spot of solder. The tools required are a soldering outfit and combination pliers.

Altering a Magneto.

I have just bought a magneto, type DAv, for a twin Minerva. The magneto is intended to run anti-clockwise, but the engine driving connections run clockwise. Would you kindly let me know whether I can run the magneto clockwise without damage? If it is not possible to do this, would you let me know why?—F.E.H.

To render the magneto suitable for your machine it will be necessary to purchase from a dealer in magnetos a contact breaker designed to run in a clockwise direction. The contact breaker and the cams which operate it are the only parts of the instrument which decide which way it is to run.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY.

During 1918 the restriction on the import of paper and paper making material is very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week

Overheating.

I have a 3½ h.p. Kerry-Abingdon fitted with a B.S.A. carburetter and geared 4½ to 1, which runs very well on the level, but seems to lose power on hills and get very hot. The compression is fair, the valves are ground in, there is a very small shake in the connecting rod, the timing seems correct, and the magneto is adjusted with the lever retarded when the piston is at the top of the stroke. I drive with the spark fully advanced, the throttle three parts open, and about half-air. I should be grateful if you would tell me what is wrong and answer the following: (1.) Is the gear too high? (2.) A friend of mine has a 2½ h.p. two-stroke; should I be able to climb the same hills if my machine is geared the same? (3.) Should I retard the spark on hills? —F.B.

(1.) The gear is somewhat on the high side. (2.) Certainly you should be able to climb the same hills as a 2½ h.p. two-stroke. (3.) Retard the spark on hills if the engine labours or shows signs of distress. Also try the effect of a smaller jet and use good lubricating oil.

Pressure Tank for Coal Gas.

Owing to the present petrol restrictions, I propose making two sheet steel cylinders (5ft. long × 6in. diameter), and run them parallel with my machine, to extend well behind the back wheel, so as to allow movement of the front wheel. Will you kindly tell me how much gas the above cylinders would hold at 80 to 100 lb. per square inch pressure, and how many miles I ought to get from the above when fully charged, my machine being a 2¾ h.p. twin Enfield? Also, would it be necessary to fix back pressure valves between cylinders and engine?—H.H.

The capacity of each of your cylinders at the pressure you suggest would be about six cubic feet. The distance this amount of gas would run you depends entirely upon your fuel consumption in the ordinary way of things. Two hundred and fifty cubic feet of coal gas are equivalent to about one gallon of petrol; thus if your machine does normally 100 miles to the gallon, on the twelve cubic feet of coal gas that you have available it should do about five miles. You would require a pressure reducing valve between the gas containers and the engine, and also a gas reservoir. The tank might be utilised to function as the latter.

Difficulty in Removing Cylinder.

I recently bought a second-hand 8 h.p. twin J.A.P.-engined machine. In attempting to take off the cylinder the other day, I found that it would not come off. It will come until the bottom of the piston appears just below the base of the cylinder about half an inch, but not further. Please let me know if there are any means of getting the cylinder off without doing any damage. I tried paraffin and oil for several days, but it does no good.—M.C.

It might be possible to remove the cylinder by tapping the mouth of it gently with a wooden mallet, or it ought to come off by lifting and twisting at the same time. If this method fails, the only remedy is heating the base of the cylinder evenly all round with a blow-lamp. The engine should, of course, be removed from the frame.

Making a Small Water Injecting Valve.

I have seen many letters in your excellent journal from motor cyclists who have been enabled to use petrol substitutes by fitting a device for letting water drip into the cylinder through the compression tap. I also hear that this is a cure for pre-ignition and knocking. I want to fit such a device on my own machine, but I cannot see how to do so without losing compression. I have fitted a sparking plug with the electrode taken out in place of the compression tap. This, when joined to the copper pipe from my spare tank, forms a free channel for the water to flow through; but I see that I need some sort of valve. (1.) What is a needle valve? (2.) Is it a needle valve that I want? (3.) Please tell me how to make or where to get the valve you would recommend. I clearly see that I must fit some device so that the compression stroke cannot force the mixture up the water pipe, also so that the suction stroke cannot suck too much water into the cylinder. (4.) Please explain how the device works.—Enterprise.

(1.) A needle valve is a valve consisting of a single shaft with a pointed end ground into a cone-shaped seating. (2 and 3.) We should say the valve in question should be of the mushroom type, with a fairly strong spring, so that it would open on the suction stroke of the engine and allow a drop of water to pass, and would close again on the compression stroke. Unless you are a very clever amateur mechanic you will not be able to make such a valve. It would have to be turned up accurately. And also the seating of the valve would have to have the correct angle, a suitable non-rusting spring would have to be provided, and the parts would have to be all of brass. It would be a much simpler matter to utilise an old carbide generator and introduce your drip into the induction pipe, when it will be drawn into the engine with the charge. (4.) The success of the former device would depend very much upon the tension of the spring, as it is by controlling this that you would be able to regulate the quantity of water allowed to pass through on the suction stroke.

Improving the Silencer.

(1.) My silencer is quite empty. Is there anything I could fit in it to check the rather loud exhaust? The silencer is in front of the engine, and is fitted with a long back pipe. (2.) How far should the points of a magneto be apart for a $4\frac{1}{2}$ h.p. Singer with sidecar? (3.) I have had my carburetter repaired by the makers, but can only start up with the lever half open, when the machine will run all right; if I stop up the fixed air intake at the bottom with rag it will start quite easily with the lever barely open. Could I fix anything to open and shut the intake for easy starting? (4.) The clutch is on the engine-shaft; I have washed the plates. Should I begin to replace with a brass or steel plate? There are two steel plates, marked with "F's" over them. Does that mean they should be outside? If so, there are two brass plates one end running together.—D.W.S.

(1.) If you put anything inside the silencer, you are likely to throttle the exhaust, and consequently we should recommend either a longer extension pipe or that you flatten the end of the existing extension pipe, and cut about six vertical slits in it about 2in. apart, the first being about 3in. from the flattened end. (2.) .4 mm. (3.) This may be due to the bad petrol we are getting at the present time, or to the fact that rather too small a jet is fitted. If there is an air leak at the carburetter or induction pipe unions, this would cause the machine to start badly. Of course, you could easily fit a shutter to the fixed air intake of the carburetter, but this should not be necessary. (4.) The clutch should be assembled so that the bronze plates are in contact with the steel ones, *i.e.*, alternate bronze and steel. Probably you will start off with a bronze plate, as the body of the clutch will be of steel.

Knocking Under Load.

My machine runs all right in all three gears on the stand, but when out on the road I get a nasty knock on top gear as soon as I come to a bit of a hill, and yet I can climb anything I come to on second gear without any sign of knock. The machine used to run smoothly enough on top gear over anything. I have taken the cylinders off and cleaned the pistons, and the rings are all right. I have tried new plugs, have cleaned the carburetter out (Amac 32 jet), and have tried retarding the spark, but still I get the knock. The machine runs well on the level, but as soon as I come to a rise I get this nasty knock.—W.L.

Your gear is too high or the magneto is timed too early, or else you are using a plug which is unsuitable and causes pre-ignition. Present-day petrol might cause the knock, and the fitting of a cardboard joint, about the thickness of a dozen pages of *The Motor Cycle*, between the cylinder and crank case, would have the desirable effect of reducing the compression.

How many Miles per Cover?

A TYRE is worth the mileage it gives you—not what you pay for it. If you would know the value of a tyre (how it wears, if it is easily punctured or cut) you must ask a user of that Tyre—Many users of Beldam All British Tyres have recorded their experiences in a little Booklet entitled "Testimony," which will be sent post free on request. It will help to make clear to you why "once used always used" applies to Beldam Tyres, and that Quality, which means good service, always counts. It is because of the high quality of design, material, and workmanship that Beldam Tyres wear so long, and give such satisfaction.

Retreads

INVEST in a Beldam Retread: it will save you nearly the cost of a new tyre.

"I have done over 5,000 miles on the last retread you did for me about twelve months ago. I think it is money well spent in Beldam Retreads."
—A. G. W.

Send old covers of any make and we will quote you cost of retread.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☛ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller. but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

200 MOTOR CYCLES & CARS IN STOCK ! !

RIDER TROWARD & CO

Just before Xmas last we advertised in this paper a list of 120 odd Motor Cycles and Cars for sale. Certain sceptics, for reasons of their own, have asserted that we have never had as many as 120 machines and cars in stock at one time, and that we advertised machines we had not got. For their benefit we state that our present stock for sale is **201**, which we shall be pleased to prove to any caller under **£100 penalty**, to be given to any charity. This week we advertise in the small columns **59** different makes, totalling 124 machines—a selection only of our stock, which we rightly claim to be the largest in England. If you are wanting ANY MAKE of machine, look for our advertisement under correct heading in miscellaneous small advts. to-day. If the machine you require is not there, write to us to ask why.

Any machine advertised SOLD ON INSTALMENTS, quarter down, balance to suit purchaser, provided machine remains with us till paid for; garaged and insured free. An excellent opportunity is thus offered to obtain a good machine now at moderate price, before the end of the War, and the consequent rise in prices. BE READY to ride the moment Peace is declared, and secure your machine now. Any machine not suitable changed free within fortnight of purchase, and taken back in 12 months at £7 depreciation in part payment of a new model. Full lists free. Exchanges. War stock accepted

A High or Low Centre of Gravity and its Probable Influence upon Side-slip.

IN *The Motor Cycle* of last week there appeared a sketch of a very original motor cycle, having a five-cylinder rotary engine and a gear box placed immediately below the saddle. These two points, combined with the large size of the steering head, indicate a high centre of gravity, and it may be interesting to consider briefly and without going into mathematical details what effect this is likely to have upon side-slip. We remember that it was once stated that, as a motor cycle would be absolutely stable if its centre of gravity were below the point of support—*i.e.*, the road surface—it was desirable, in view of the impossibility of attaining this ideal to keep the centre of gravity as near the road as possible. This, of course, is incorrect. One of the means of maintaining the balance of a single track vehicle is by altering the position of the points of support, so that the straight line between these shall always be directly under the centre of gravity. Let us take a sledge hammer as an example. If this be balanced on the finger with the head upwards it will be found perfectly easy to keep it in an upright position, but if the shaft be placed uppermost the balance will at once become very difficult, and will require considerable skill. This is, of course, an extreme case, but it disproves the statement just quoted, and suggests that for easy balance it is not desirable that the centre of gravity of a motor cycle should be too low.

There is, however, another aspect of the case. When a motor cycle is being well ridden in a straight line along a smooth but slippery road, it will not side-slip because no force is present to cause it to do so, but when the wheel meets an obstruction which forces it in a sideways direction we encounter a new set of conditions and see why it is desirable that the weight should be kept low down. Again, let us take the analogy of the sledge hammer. If this is suspended head upwards by a piece of string a slight push or tap on the end of the shaft will result in considerable lateral displacement, but hang the hammer up by the shaft and it will be found that even a hard blow on the head has little effect. This shows that a low centre of gravity is able to resist the side thrusts caused by obstructions, and thus it enables the motor cycle to maintain a straight course.

The whole question is one of the best compromise. When the centre of gravity is high the wheels are more easily deflected from their course, but given a certain deflection, say three inches, the machine and rider are placed rather less out of the vertical than would be the case if the centre of gravity were low, and balance is more easily regained. This, however, does not exhaust the matter, and we have to remember that a motor cycle which has begun to slip will be much more likely to continue to do so than that a slip should be set in motion in a machine which is steadily following its true path, owing to the difference between static and sliding friction. Our object must therefore be to arrest all tendency to side-slip at its origin.

To sum up, we are of opinion that, inasmuch as it is an easy matter to maintain balance so long as the wheels grip the road, it is best to keep the centre of gravity fairly low, but not to go to an extreme.

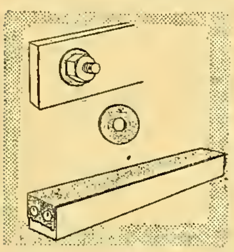
We have not thought it well to discuss gyroscopic action, centrifugal force, and cornering here, as we have in hand articles on these subjects written by our technical contributors, but our endeavour has been to put forward a few simple thoughts in simple language, and we should be glad to have our readers' opinions on this important question. The general tendency is, and we think rightly, towards the provision of a low centre of gravity.

An index to the advertisements in this issue will be found on the page facing the back cover

IDEAS: Useful and Ingenious.

USE OF EMERY CLOTH.

IT is best to procure engineers' emery-cloth. This has a number of uses in the motor house. If a spring washer is required to secure a nut which insists upon getting loose, and one cannot be found, a washer cut out of emery-cloth will often do just as well.

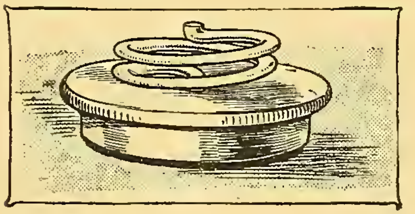


An improvised tool sharpener and spring washer

A useful tool for smoothing down flat surfaces for sharpening tools or for polishing the heads of pistons can be made by cutting a strip of emery-cloth, say about two inches wide, and fixing it on to a block of wood a good inch shorter than the cloth. The ends of the cloth should be then bent over and secured to the block by means of drawing pins.—*L'Automobile aux Armées.*

VENTING A PETROL TANK

A FOOLPROOF arrangement for venting a motor cycle petrol tank may be made from a helix of $\frac{1}{4}$in. diameter brass pipe soldered into the filler cap, two complete coils being found quite sufficient.



The helix of brass piping used as vent for a petrol tank.

I have been using it for some time on my own motor cycles—first a Rudge, and now a Douglas, fitted exactly as illustrated, and found it very satisfactory.

When I first thought of the idea I fancied it was novel, but, on investigation, I find this is not so, as a similar arrangement was used by the Vauxhall people on the radiator filler cap on their Grand Prix cars.

I never appreciated how much fuel was being lost on my Rudge until one day, being short of petrol, I filled up with a quantity of paraffin. Almost immediately leaks showed everywhere—at the doping cock, at the main cock, and at the filler cap, but the last-named was much the worst, and the leak from it was sufficient to cause drops of fuel to collect on the side of the tank, and these were blown back on to my legs.

Now I can fill up, if necessary, right into the bung of the filler without a drop coming out. On the Douglas I have removed the glass window from the filler cap and soldered a brass plate in its place, which carries the vent pipe shown. At the same time I have soldered up the existing vent hole, which was drilled about half-way up the threaded portion of the filler which is soldered to the tank. —F.G.S.

FITTING A HOT AIR INLET.

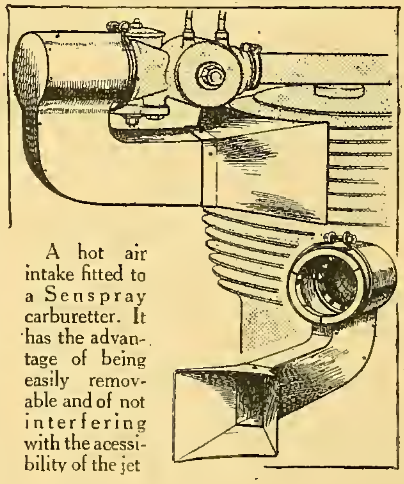
THE sketch illustrates a hot air inlet which has been fitted to the air inlet of a Senspray carburetter on a $3\frac{1}{2}$ h.p. Rudge motor cycle.

This fitting has been in use since early last year with quite satisfactory results, and even in the summer time there was no necessity to remove it.

It simply slips into place on top of the existing portion of the Senspray carburetter, which carries the gauze sleeve, this gauze being left in place.

To get at the jet the only thing necessary is to slack off the screw of the clamping band, when the whole fitting can be swung round in an anti-clockwise direction, viewed from the rear, leaving the hexagon head of the jet easily getat-able.

The fitting actually illustrated was made from 22 S.W.G. sheet aluminium, flanged and riveted together with $\frac{1}{16}$in. copper rivets. This makes a very neat construction, but quite good results can be obtained by using ordinary sheet tin and soldering along the edges.



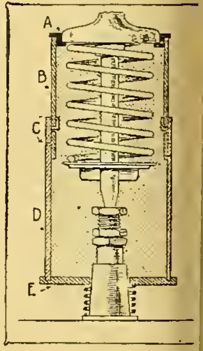
A hot air intake fitted to a Senspray carburetter. It has the advantage of being easily removable and of not interfering with the acessibility of the jet

Careful consumption tests were mad in the summer over a distance of 128 mile on a dry, but by no means easy, cross country trip, and it was found that th machine was doing 92 m.p.g. at an al through average of 28 m.p.h.

Owing to the construction of the carbu retter, all the incoming air is nicel warmed, and the whole of the blow-bacl is trapped and made to furnish its shar of the mixture.—F.G.S.

USEFUL VALVE COVER.

A CAPTAIN in the Royal Engineer sends the following description of valve cover he has found useful He says: "The valve covers were mad for a 1915 Triumph I ride here in France They have been in use six weeks now, and are very efficient and neat. Although the idea may not be new, I send you the sketch in the hope that it may prove useful to some readers of your splendid paper. I think the drawing is more or less self-explanatory, but append list of parts lettered in.



A convenient valve stem cover

"A. Brass ring turned Z section to fit top cup and inside diameter of smaller brass tube.

"B. Length of $\frac{1}{16}$in. brass tube.

"D. Length of $\frac{1}{16}$in. brass tube to exactly over B.

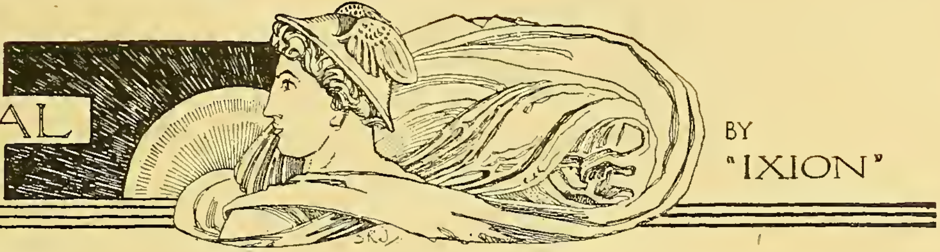
"E. Brass disc to fit over tappet guid and with slot provided for lower end of

"C. Quarter-inch piece of tubing as Cut in half, and with two L-shaped stu in each half. These studs engage in slo cut in B.

"The coil spring is to put pressure the whole."

AN INFLATION TIP.

A TIP picked up in Australia, whi has saved a good many long wall if not a few lives (the distan between water being so great in t Never Never Land), is that a tyre c easily be inflated without the aid of pump connection. One thickness of —a handkerchief, say—is interposed tween the valve and pump where t connection usually fits. The air pas readily enough through one thickness handkerchief, and if the pump is h firmly against the valve scarcely a air escapes.—D V LESTER, Hatfi Peverel



OCCASIONAL COMMENTS

BY "IXION"

Over-gearing.

SEVERAL recent correspondents have been trenching on the old controversy of overgearing *v.* undergearing. Before the war anybody who bragged of having covered a long hilly run without a gear change was immediately classed as a liar or accused of grossly undergearing, according to his personal reputation and the route covered. On the other hand, anybody whose front pulley emulated a bread trencher in diameter, or whose front sprocket seemed to be swanking it over the countershaft sprocket, was scoffed at for overgearing. The "undergearing" school seems to have influenced the trade. In the old days the 3½ h.p. solo machine was usually sent out with a gear of about 4 to 1. This ratio was not very useful in hilly districts, but it gave you a nice margin for running the belt in. By the time you had got the stretch out, you were usually down to about 5 to 1, as the average amateur generally shortened not wisely but too well. Having arrived at the lower ratio, you found the machine climbed better, and did not require quite so many miles in which to whack up to its maximum; so you stayed there till you sold. When the trade ratted to the belt-cum-chain or all-chain drive, ratios became less elastic. The harshness of the drive, and the fear of conks at low speeds and in picking up, inspired a general reduction of top gear ratios, for which the sidecar also bore some responsibility, and of late years several 3½ h.p. and even 5 h.p. twins have been delivered to me with fixed top gears of 5 to 1, or even less. If my top gear is fixed, I must say that 4¾ is my preferential maximum for a 3½ h.p. or 5 h.p., and 5½ for a 350 c.c. This, of course, is where a really good four-speed gear comes in. My present mount is of that character, and possesses a normal top gear of 5½, which is actually its second ratio (*i.e.*, third speed). In reserve above that is the freak top gear of 4½, to which one very seldom troubles to change up, unless faced by a longish piece of very favourable road. Of course, a box of this kind is simply a nuisance, unless it is very, very good. If it is noisy or frictional, your normal top of 5½ is spoilt, and though you can occasionally find use for a freak top of 4½ to 1, it is not worth sacrificing either efficiency or silence on the 5½ to get the 4½.

Where Three Speeds Score.

THE real blessing of three speeds is specially recognised in driving sidecars and the 350 c.c. solos. The 2¾ h.p. Douglas used to be equipped with two gears of about 5½ and 8¼ respectively, and any owner who ventured in mountainous country with his engine a "wee bit saft," soon found himself sighing for a lower ratio. To start with, the Douglas people built a few competition mounts with two gears of 5½ and 11½, or thereabouts; and the weakness of this system was felt in moderately hilly districts; the high was too high, and the low was too low. Much the same applied to driving the staunch old P. and M. with a sidecar attached. There was no intermediate stage between conking out on the top and grinding away painfully on the low ratios, 5½ and 11, as near as I can remember. Sidecars and little 'uns want three gears; and want them in the sense of being very decidedly imperfect with less. I daresay our Scottish critic will agree?

Will there be Any for US?

THERE is a distinct chance that motor cyclists will soon feel the need of a strong association to watch over their interests more than they have ever felt it before; and the A.C.U. may be given a unique chance to make good. Rumour threatens that all ordinary war workers will be completely deprived of petrol by June at the latest, and offered gas as a substitute. As far as I know, very few solo riders still possess petrol permits; but there are some survivors, and their need of fuel is presumably acute, or they would have been combed out long ago. We cannot use gas; it is an infernal nuisance on sidecars, and absolutely out of court, at present, in solo work. When the new restrictions are drafted, taking it for granted that rumour for once is not lying, will the case of the solo motor cyclist be considered? I speak quite disinterestedly, as the matter does not affect me personally in the least.

Inconsistencies.

AS a matter of fact, there are many loopholes remaining in the control of fuel, as it exists to-day. For example, I know of a certain munition factory—I must describe the case "diagrammatically," as the draughtsmen say, for certain reasons, and can only give a general idea of it. Let us suppose that the designer, the works manager, and the buyer of materials all legitimately require the assistance of a motor on occasions; that, conceivably, circumstances may arise when all three must travel in different directions simultaneously, and at great speed. It would nevertheless be absurd to allot these magnates a very powerful car apiece, when a small one would do. It would be absurd for them to travel a mile from their private residences to the works by car two or three times per day. It would be absurd for them to use cars instead of trains, if their works are close to a main line with as good a service as one can expect in these days. At least, all these things would be absurd if the shortage of petrol is as acute as other regulations imply. There is no denying that most of the discontent about fuel restrictions arises from *contrasts*, from uneven handling by officials of two similar cases.

The Late Mr. H. Walter Staner.

A Tribute by Sec.-Lt. G. Geoffrey Smith, R.F.C., Late Editor of "The Motor Cycle."

A STAUNCH champion has been lost to motorists and the motoring movement in general by the death of Mr. H. Walter Staner, for seventeen years editor of *The Autocar*. By the irony of fate he has been called away to the great Unknown at a time when so many of his colleagues who had learned to love him are scattered the world over; some, too, who owe a successful career largely to his kindly encouragement and help. Many will not learn of his sudden and sad departure until long after his mortal remains have been laid to rest, but none the less real will be the pangs of regret at the loss of such an esteemed leader and friend.

To those more intimately associated with the late Mr. Staner, the task of offering a fitting tribute becomes the harder, for acquaintanceship in this case will remain a permanent and glorious memory. Ever ready to encourage and assist, willing at all time to give a sympathetic hearing to young or old, whatever their position, duty with Mr. Staner dissipated many of life's worries. His charming manner, his considerate treatment of all subordinates, his ready help and guidance, won for him the respect and esteem of all. Mr. Staner possessed a receptive mind and the highest ideals; no suggestion, however extreme, failed to receive due consideration, and he unstintingly meted out praise where praise was due. The more difficult the problems that confronted him the more he seemed to revel in their solution; what had originally appeared a mountain became the proverbial molehill under his intuitively sagacious handling.

The late Mr. H. Walter Staner.

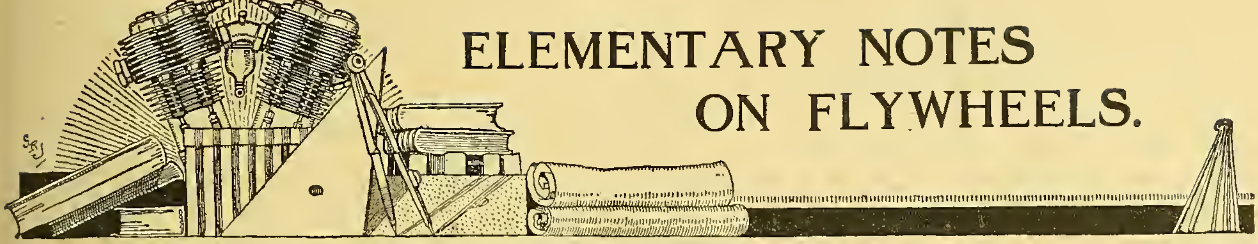
To the great army of motor cyclists Mr. Staner was known only as Editor of our parent journal, *The Autocar*, but behind the scenes he played a greater and more active part in the motor cycle world than was apparent to the ordinary beholder. He it was who forecasted the future of the four-cylinder motor cycle as long ago as 1905; and it was not long afterwards, at another dinner of the Auto Cycle Union, that he proposed a Tourist Trophy Race for motor cycles—a suggestion which was adopted the following year, with what result we all know, for what is a year of peace without a motor cyclists' T.T.?

Since Mr. Staner was a great admirer of mechanical efficiency, his ideal motor cycle was none of the variably geared clutch model mounts; his admiration was reserved for the light sporting T.T. mount shorn of all unnecessary impedimenta—a thing of life, instantly responsive to the throttle. The same ideals he cherished in the car world, and in conversation, when indulging in flights of fancy, he would constantly refer to the light T.T. motor bicycle being exemplified in cars ere long. Time will show whether his prognostications will become accomplished facts. Sluggish, inefficient machines he abhorred. One of his most laughable sayings—and he frequently used the most amusing expressions, full of meaning by way of illustration—was that the pressing of the accelerator pedal on a vehicle with a sluggish, woolly engine was like kicking a blancmange—a most expressive phrase, but one which would not occur to everyone.

Far seeing and quick to grasp the possibilities of any new design, however freakish it might appear to less imaginative people at the time of its introduction, he always perceived its real merits and gave words of encouragement to inventors which helped forward subsequent developments. How many standard features of modern cars owe their rapid development to Mr. Staner's fertile brain it would be difficult to say. The four-cylinder engine, the low flush-sided body, the sloping dash, the gate change, the four-speed gear—all received his unstinted approval at the time of their introduction years ago, and their rapid adoption was in no small measure due to his advocacy. Although he was never at any time enamoured of the cycle car, yet he cherished a sincere regard fo the air-cooled engine, and was optimistic as to it adoption on cars in the future.

One of his pet ideas was an air-cooled radial-typ engine placed between the driver and front passenge as on the old Lanchesters. Never tired of discussin engineering problems, he was as much at home o locomotive and steam engine practice as he was on car and motor cycles, and his wide study and soun judgment on all questions mechanical rendered him tower of strength.

Mr. Staner's greatest pleasure consisted in givin pleasure to others. In matters remote from busine his advice was sought and obtained in the friendlie possible manner. Courtesy, kindness, and co sideration for others were realities to his nob mind. To think that he is gone touches t deepest emotions. His was a noble life: an exampl an inspiration.



ELEMENTARY NOTES ON FLYWHEELS.

Some Notes and Personal Ideas on Flywheels in Theory and Practice, including a Few Arguments in favour of the Outside Flywheel.

EVERY motor cyclist of understanding realises as time goes on that the outside flywheel will become more and more the common order. Its employment in connection with internal combustion engines for vehicle propulsion dates back, although it may be assumed that the system really became popular in motor cycle design with the Douglas and two-stroke lightweight. It was adopted in the case of the latter on account of the fact that it admitted of a crank case of small capacity, which simplified matters in connection with crank case compression. Similarly, the outside flywheel was adopted for the flat twin on account of the double-throw crank, which in itself was of considerable width, so that it was found convenient to place the flywheel on the outside of the driving sprocket, rather than build the crank case of sufficient width to receive it.

This—on the outside of the drive—is the proper place for a flywheel. In one or two freakish instances it is placed on the opposite end of the crank to the driving wheel, with the result that the stresses on the crank are reversed at every impulse of the engine, thus demanding a very much heavier crank if the risk of whip and breakage is to be eliminated.

Advantages of the System.

So far, however, the outside flywheel is practically limited to two-strokes and flat twins, but its general application to other types is only a matter of time. It will be recalled that the single-cylinder Blackburne—an engine most remarkable for its even torque and steady pulling on gradients—employed an outside flywheel, as also did the Premier 90° twin and the Buckingham twin.

What are the distinct advantages of the outside flywheel compared with the inside type? Foremost may be set down the elimination of oil friction. The inside flywheel is always in contact with the oil contained in the crank case, with the result that an overdose of lubricant causes excessive friction. Riders of long experience who can recall the early types of inside flywheel engines, with their shallow crank case clearance, will recollect clearly how the least indiscrimination in administering the oil led to a loss of power. The fact that insufficient space was left between the flywheel and the inside of the crank case resulted in the flywheels being constantly retarded by the oil, just as a spinning cycle wheel would be retarded and quickly arrested if immersed in a trough of water. This, then, makes it clear why quicker acceleration and steadier pulling are more possible with an outside flywheel than with the inside type.

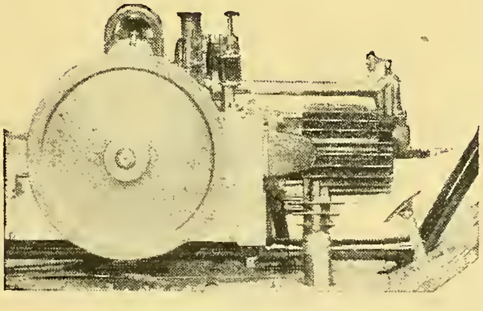
The Douglas.



The Wooler two-stroke.

TYPES OF MODERN ENGINES FITTED WITH OUTSIDE FLYWHEELS.

Weight of Flywheels.

The question of weight also enters into the matter.

The flywheel is the heaviest component in the construction of the engine, and therefore it is the first point at which to aim in attempting to reduce weight. Clearly, the kinetic energy of a flywheel is dependent upon two things—the weight of its periphery and the distance from the centre at which the weight takes effect. Thus a flywheel having its weight one foot from its centre—that is a flywheel two feet in diameter—would be more efficient than one 6in. in diameter, even though the latter were fourteen or fifteen times the weight of the other.

By employing an outside flywheel we are not limited as to its diameter, so that, instead of making it stumpy and heavy, we can make it wide and light, having most of its weight near the periphery.

Naturally, the weight of the flywheel necessary depends upon

Elementary Notes on Flywheels.—

the impulses of the engine. A 1,000 c.c. single-cylinder engine would obviously require a flywheel four times the weight of a four-cylinder 1,000 c.c. engine. In every-day practice we have an example in, say, the Scott two-stroke with its even torque and its flywheel weighing approximately 14 or 15 lb., and the 4 h.p. Bradbury, or any other of similar type, the flywheels of which probably each weigh something in the vicinity of 28 or 30 lb.

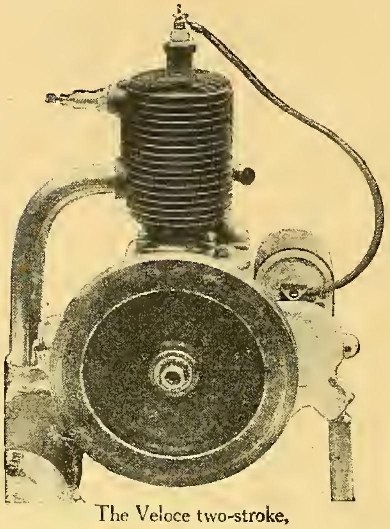
The Four-cylinder Type.

The four-cylinder Henderson is among the lightest motor cycle power units on the market for its capacity, while the single-cylinder is the heaviest type that can be reached.

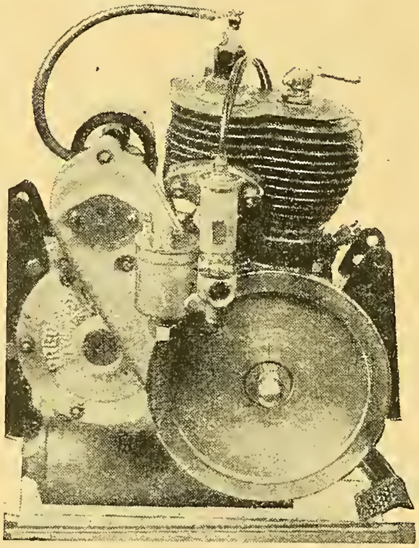
In practice the most suitable weight of flywheel depends largely upon the work for which the machine is intended. Fixed rules, of course, are laid down which can be safely followed, but most engineers prefer to ignore them and work according to their own ideas. For instance, a single-cylinder machine for sidecar use would be far more satisfactory for that purpose if it possessed a flywheel capable of high kinetic energy—which, for brevity's sake, we will refer to as a heavy flywheel—than if it possessed one on the light side. The flywheel acts as a shock absorber, and absorbs as it were the thrust of the power impulse, delivering it evenly over the succeeding 1½ revolutions, so that the heavier the flywheel the less violently is the power impulse imparted to the transmission, and the more evenly is it delivered over the succeeding 1½ revolutions. It assists also in hill-climbing, for when high "revs" have been obtained a heavy flywheel naturally helps the engine in keeping up its beat on a gradient of short length. If, however, the gradient continues and the "revs" steadily fall, the weight of the flywheel is no longer an advantage.

High Kinetic Energy.

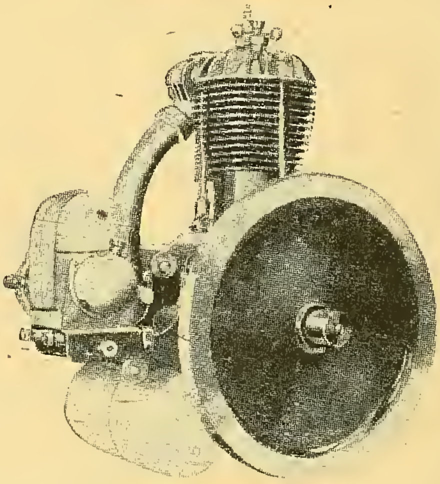
A flywheel with high kinetic energy is desirable for sidecar machines from another point of view; in that it enables the engine to take up the load from a standing start without undue strain. Every rider of a Scott, or, say, a Brough, knows that he must be careful how he lets in his clutch, as the engine can be brought to a sudden stop by careless manipulation owing to its light flywheel. On the 4 h.p. Bradbury already referred to, however, an easy start is assured, even though it be attempted on a severe gradient or the clutch let in rather roughly. Similarly, a heavy flywheel, which acts as a natural reservoir, saves the tyres and the transmission throughout—in fact, adds to the general durability of the machine, though it naturally renders very rapid acceleration impossible. Therefore in racing machines the weight of the flywheel is cut down, so that they can move rapidly off the mark and pick up instantly after slacking at corners.



The Veloce two-stroke,



The Precision four-stroke.



The Blackburne four-stroke.

TYPES OF MODERN ENGINES FITTED WITH OUTSIDE FLYWHEELS.

Economising in Material.

Much yet remains to be done in motor cycle design in economising weight and material. The ordinary inside flywheel machine is a very poor example of economy in these directions. In four-cylinder design the flywheel is, at any rate, utilised in functioning as a member of the clutch, but in ordinary motor cycle practice not even this economy is attempted. Nor is it particularly desirable. It is better that the clutch should run at half engine speed than full engine speed, and therefore taking into consideration the proper distribution of weight the countershaft is undoubtedly the best place for the clutch.

The flywheel, however, might be used for another purpose, viz., for generating electricity for lighting and ignition, as is already done in the American motor scooter. We should thus do away with two weighty units—the magneto and the dynamo. We should employ, of course, a coil for ignition purposes in accordance with American practice, and the lamps could be lighted directly from the flywheel. Doubtless this will come in time, and having taken all these points into consideration there is no doubt that the outside flywheel not only tends in the direction of higher all-round efficiency, but lessens the weight considerably.

Summed up briefly the conclusion is: We find it desirable for efficiency to employ a flywheel of ample width; this cannot be done with the inside type, because there is not room for it, and because the wider we make it the greater the loss by oil friction. CHINOOK.

B.S.A Popularity

and why–

PERFECT FINISH.

A typical example of the thoroughness of B.S.A. methods is the unrivalled finish which distinguishes all B.S.A. productions. Even the smallest detail of B.S.A. Motor Bicycles bears emphatic proof of the claim "Perfect in every Part." B.S.A. finish is the final touch to perfect material and workmanship, and is undoubtedly one of the features which make B.S.A. owners so justly proud of their machines. Besides possessing the merit of attractiveness, B.S.A. finish has proved its durability. Under severe riding conditions it both wears well and is extremely weather resisting.

SOME NOTES ON H.P. OF PETROL ENGINES.

Interesting Tables and Formulæ showing how the Power Output of a Motor Cycle Engine is Utilised.

For finding the h.p. developed by an engine there are three well-known ways, (1) by means of a brake test, (2) by driving an electrical generator whose efficiency at any output is known, and (3) by the use of an indicator. As regards steam engines, No. 1 is seldom used, No. 2 occasionally, and No. 3 most often. The indicator diagram being also of great use in verifying the setting of the valves, it is even more used for this purpose than for calculating i.h.p.

With petrol engines different forms of the brake test are employed, but the prominent manufacturers use the electrical method (No. 2), as being more suitable for turning out batches of engines to a certain standard, the indicator being only used for research work on a particular engine. Owing to the great number of revolutions per minute of the small petrol engine, it was some time before a satisfactory indicator diagram could be obtained, but a few years ago a beautiful and accurate instrument was devised which overcame all difficulties.

Fig. 1 shows an indicator diagram such as would be obtained from a petrol engine. The great value of the indicator diagram at the time it was first used was to show the behaviour in the cylinder of the gases with various types (high and low compression) of engines, and with variations of compression and ignition timing on the same engine.

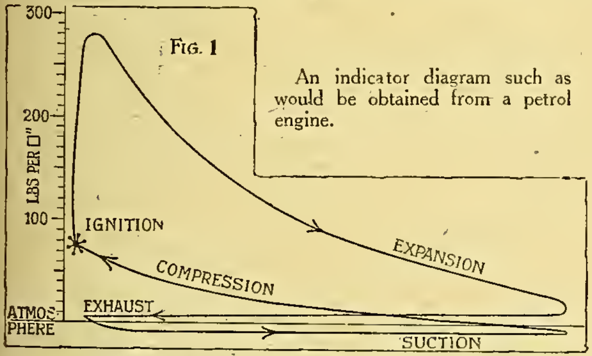

FIG. 1

An indicator diagram such as would be obtained from a petrol engine.

It is not intended to go further into this matter here than to say that it was found that in the *normal* engine at about full load an *average* pressure of 80 lb. per square inch acted on the piston during the power stroke.

It is this information which it is proposed to utilise here, and it must be borne in mind that in the figures given below the high-compressioned specially-fitted racing engine is not referred to, but only the ordinary every-day working unit such as that fitted to a touring motor cycle.

A table is given showing the calculated i.h.p. at different revolutions per minute, the engine working at about full throttle opening, so as to give the 80 lb. per square inch mean effective pressure. A gear of 4 to 1 is assumed, and the road speeds corresponding to the engine revolutions with 26in. wheels are worked out. Other calculations have been made, and the formulæ are explained where necessary. The machine is assumed to be a 500 c.c. in touring trim, weight of machine and rider 450 lb., and windage area 4.5 square feet. The proportion of i.h.p. available at road wheel is taken at 85%.

TABLE I.

Miles per Hour.	R.P.M. of Engine.	Calculated I.H.P.	H.P. Available at Road Wheel.	H.P. Air Resistance.	H.P. Available for Gradient.	Gradient the Machine will Mount.
15	775	2.38	2.02	.174	1.84	1 in 9.7
20	1033	3.18	2.7	.41	2.29	1 in 10.5
30	1550	4.77	4.05	1.4	2.65	1 in 13.5
40	2066	6.36	5.4	3.2	2 2	1 in 21.8
50	2583	7.94	6.75	6.45	0.3	
60	3100	9.52	8.08	11.2		

It will be evident that the limit of speed on the road for the machine is apparently just over 50 m.p.h. If the windage area were cut in half (as is found possible on racing machines), and a higher compression used (giving greater mean effective pressure during power stroke), a speed of eighty miles per hour is possible, as records show.

Calculation of I.H.P.

The formula given is adapted from the well-known $\frac{PLAN}{33{,}000}$. It may be used for any size of engine independently of the number of cylinders, provided the full cubical capacity is taken into account. The formula is for four-stroke engines only.

Let L = length of stroke (feet).
A = area of piston head (sq. in.)
P = mean effective pressure during power stroke.
V = engine capacity in cubic inches = 12 LA.
r.p.m. = revs. per minute = 2 N (N being the number of power strokes per min.)

$$\text{Then i.h.p.} = \frac{P \times \frac{V}{12} \times \frac{\text{r.p.m.}}{2}}{33{,}000} = \frac{P \times V \times \text{r.p.m.}}{2 \times 12 \times 33{,}000}$$

Some Notes on H.P. of Petrol Engines.—

since P for our purposes is taken as constant at 80 lb. per square inch.

$$\text{Then i.h.p.} = \frac{80 \times V \times \text{r.p.m.}}{2 \times 12 \times 33{,}000} = \frac{V \times \text{r.p.m.}}{9{,}900}$$

To facilitate calculations the following should be noted:

1,000 c.c. = 61 cubic inches.
500 ,, = 30.5 ,, ,,
100 ,, = 6.1 ,, ,,
50 ,, = 3.05 ,, ,,

Example 1.—About what is the maximum h.p. developed by a 350 c.c. engine running at 2,500 r.p.m.?

Volume of 350 c.c. in cubic inches = 21.35.

$$\text{I.H.P.} = \frac{21.35 \times 2{,}500}{9{,}900} = 5.4$$

H.P. at road wheel, say 85% = 4.6.

Example 2.—A 1,075 c.c. engine is running full throttle at 1,500 revs. What h.p. is being developed?

Volume of 1,075 c.c. = 65.6 cubic inches.

$$\text{I.H.P.} = \frac{65.6 \times 1{,}500}{9{,}900} = 9.95, \text{ say 10 i.h.p.}$$

Formulæ used in obtaining Results shown in Table I.

These include several well-known formulæ. For obtaining the h.p. absorbed by wind resistance, we have (as given in text books)

$$\text{H.P.} = \frac{S^3A}{87{,}300}$$

Where S = velocity of wind in relation to machine in miles per hour.
= on calm day, m.p.h. of machine.
A = windage area exposed. Taken in this article as 4.5 square feet for ordinary touring 500 c.c. machine. (Note.—This area is always in square feet.)

Some Practical Applications.

Example 1.—What h.p. will be absorbed by wind resistance with ordinary 500 c.c. machine at thirty miles per hour speed on road on a calm day?

$$\text{H.P.} = \frac{30 \times 30 \times 30 \times 4.5}{87{,}300} = 1.4$$

Gradients.—H.P. absorbed by gradients. (The weight of rider and machine is assumed to be 450 lb. in table.)

Let gradient be expressed as $\frac{1}{G}$ or 1 in G.

Let speed be expressed as m.p.h.

Let weight be expressed as W.

Then

$$\frac{\frac{5.280}{60}\ \text{m.p.h.} \times \frac{1}{G} \times W}{33{,}000} = \text{h.p.}$$

$$= \frac{.0026\ \text{m.p.h.} \times W}{G}$$

Example.—What is the h.p. expended due to gradient alone on climbing a rise of 1 in 10 at 20 m.p.h.?

$$\text{H.P.} = \frac{.0026 \times 20 \times 450}{10} = 2.34$$

Further problems are given which will be of interest.

(1.) With an engine developing power as shown in Table I., weight of rider and machine 450 lb., what gear would be required to mount a 1 in 5 gradient at 20 m.p.h.?

In solving this problem it is first necessary to find the h.p. required.

H.P. absorbed by wind resistance = .41 (by formula)
H.P. absorbed by gradient = 4.68 ,,
Total h.p. required at road wheel = 5.09

$$\text{I.H.P.} = \frac{5.09 \times 100}{85} = 5.9$$

We have previously seen that $\text{i.h.p.} = \frac{V \times \text{r.p.m.}}{9{,}900}$

Substituting 5.9 for i.h.p.:

$$\text{R.P.M.} = \frac{5.9 \times 9{,}900}{30.5}$$
$$= 1{,}915 \text{ r.p.m.}$$

With 26in. wheels, 1,915 r.p.m. of engine at 20 m.p.h. road speed means gear of 7.6 to 1.

(2.) In the above example, what is the probable *highest* speed at which the machine would mount the gradient of 1 in 5, and with what gear?

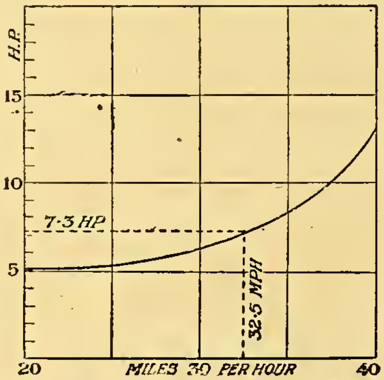
From Table I. it will be seen that the highest r.p.m. of the engine in question are about 2,800.

$$\text{I.H.P. developed at this speed} = \frac{30.5 \times 2{,}800}{9{,}900}$$
$$= 8.6$$

H.P. available at road wheel = 7.3

We have now to find the m.p.h. such that the h.p. absorbed by wind resistance at that speed, *added* to the h.p. absorbed by gradient at that speed, exactly equals the h.p. 7.3 available. This may be most conveniently done by means of a graph. To draw this three calculations must be made:

H.P. absorbed by air resistance plus h.p. absorbed by gradient at 20 m.p.h., 30 m.p.h., and 40 m.p.h.



Graph indicating the h.p. expended in overcoming wind resistance through a range of speed from 20 to 40 m.p.h.

The methods of obtaining these have been shown, so that results only are given here, the figures being 5.09 h.p., 6.42 h.p., and 12.56 h.p. respectively. Plot these as shown, and where the 7.3 h.p. line cuts the curve read off the required speed = 32.5 m.p.h.

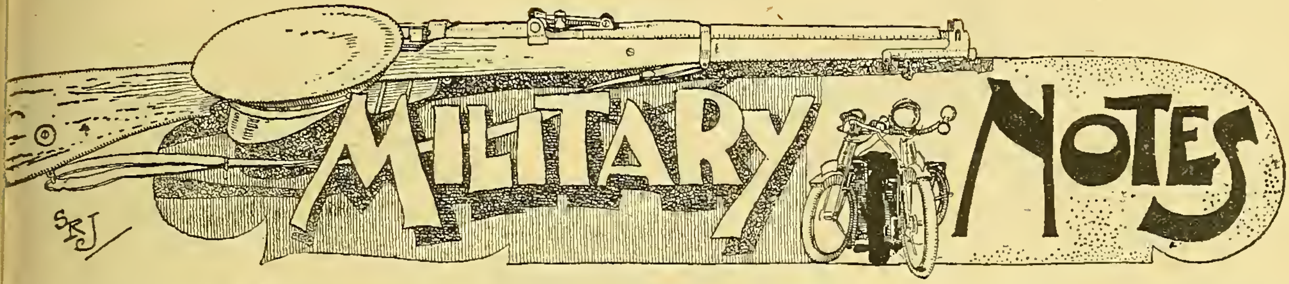
Gear necessary engine revs. 2,800 at 32 m.p.h. = 6.6 to 1.

ENGRO.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.



CAPTAIN R.F.C.

WE recently met S. R. Axford, who is now a captain in the R.F.C., and employed at home. He was a frequent competitor at Brooklands prior to the war, and when hostilities began he joined the R.N.A.S.

TANKS AND "TANKS."

THE following somewhat curious letter has been received by Mr. A. Green, manufacturer of petrol tanks, oil tanks, etc., of Water Street, Blackfriars, Salford, Manchester:

"I have just happened to see an announcement inserted by you in *The Motor Cycle* dated December 13th, 1917, referring to the repair of tanks of every description. We have quite a small number of Tanks which have been in this recent assault, and are left in our care for repair, so if you will kindly endeavour to partake of some of the work we would be humbly grateful to you. Perhaps you have seen the monstrous looking object as it was in your city a few weeks ago, and, if so, you will have some idea of the work attached to it. My address is as follows: Gunner J. Stamp, 94901, No. 2 Tank Field Company, Tank Corps, B.E.F., France. Kindly send reply, and we will send them on by parcel post."

To this letter Mr. Green has replied in the following terms:

"We are in receipt of your favour dated the 25th inst., for which we are very much obliged. The writer of this is just a little too old to help you to take part in the repair of the few Tanks just damaged in a recent assault over there. We suggest you go on killing Huns for a little more. When you have finished with the Huns, and if you will be good enough to let us know how many dozen of the Tanks you have that require our attention, we shall be pleased to send you a small case to pack them in and forward to us by parcel post. The letter has been very cheerful reading to us, seeing that the hardship you poor Byng b-hoys have to put up with, and yet you are always merry and bright. May your troubles be little ones. It may interest you to know that we have forwarded your letter to the editor of *The Motor Cycle*. We hope this will be given publicity to show the public at home the bright side of your struggle. Wishing you the best of luck and a speedy return."

NEWS OF AN A.C.U. OFFICIAL NOW SERVING.

WE have received the following letter from Pte. F. J. Briggs, who is a motor cyclist attached to a Field Ambulance in France. Before the war Briggs was assistant clerk to the Auto Cycle Union, and did much good work for, and took great interest in, the various competitions which the Auto Cycle Union then held. He writes: "I am fortunate enough to be riding a Triumph motor cycle at present, and must say that the roads near this portion of the line are exceptionally good, which makes riding a pleasure. The copy of *The Motor Cycle* which I receive weekly is perused with interest by several men in this unit, most of whom have not yet ridden a motor cycle but hope to take up motor cycling as a pastime *après la guerre*. Have you heard from Mr. Beasley (formerly assistant secretary of the A.C.U.) lately? I received a letter from him just before Christmas, and was sorry to learn that he had been suffering from rheumatic fever. I eagerly await the post-war reliability trials, as I firmly believe that the riding experience gained on Active Service will tend to make competition even more keen than it was in pre-war days. The English roads will be 'child's play' to men who have for the past three years ridden over *pavé* and through the awful mud of the Somme in November and December, 1916."

WHO IS THE OLDEST D.R.?

FROM Robt. Harvey we have received the following letter, and we should imagine it will be difficult to find a better record when age is considered:

Sgt. Robt. Harvey.

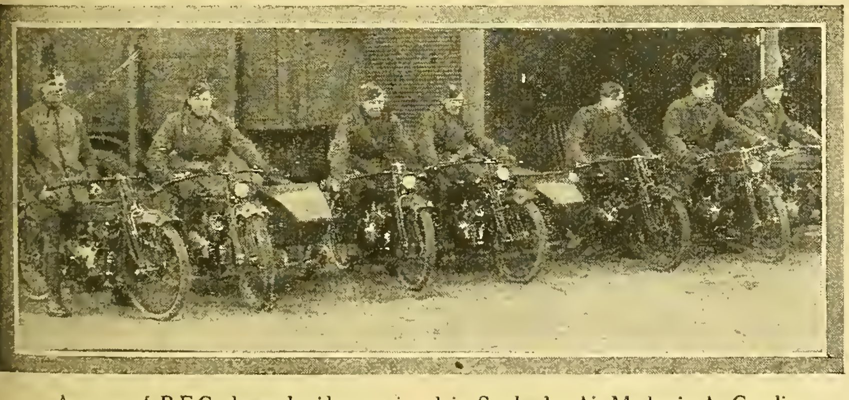
"The enclosed portion of *The Motor Cycle* has been handed to me by a D.R., who thinks I must be the oldest D.R. and suggests that I write to you.

"My age is 49½. I signed on on August 5th, 1914, and was called up on October 22nd, 1914. Since then I have served without a break, making three years and three months. Out of that I spent fourteen months in France. I was with the 38th Division on the Ypres Front, and came back to England on September 25th last.

"I left the 25th Battalion City of London Regiment at the latter end of 1910, after having served for twenty-four years in the Regulars, Volunteers, and Territorials. My age was 46 when I re-enlisted."

FLYING IN A DERELICT AEROPLANE.

LT. BERTIE C. R. GROOMWOOD, R.F.A. and R.F.C. (M.C.), was severely wounded in the air by a shell which destroyed his wireless apparatus. His machine was so badly damaged that no expert would have believed it could hold together in the air, but, in spite of this and of his wounds, he wrote out a message reporting the position of the enemy, and dropped it on D.H.Q., who were able to put nine batteries on to the target.



A group of R.F.C. despatch riders stationed in Scotland. Air-Mechanic A. Cuvelier (third from left), who sends the photograph, says they have had the "worst weather in the Isles," but the machines (P. and M.'s) never failed.

Present of a Car to a Hospital.

A motor car has been presented to the Great Northern Central Hospital, for the transport of patients.

Good Work and Funds.

This hospital, situated in Holloway, is the largest medical charity in North London, has a very wide London area to serve, as well as being open for patients from any part of the country, and is urgently in need of funds. We have no hesitation in asking readers to help this institution

The Motor Transport Volunteers.

The headquarters of the Motor Volunteers, that excellent body which transports troops on leave by motor car, motor lorry, and motor cycle in the dead of night, when the tubes have stopped running, from one London terminus to another, have recently been changed to 225, Oxford Street, W. They are in urgent need of recruits who are drivers of motor cycles, or who are willing to avail themselves of free tuition in the driving of motor lorries. The only expenses involved in joining the corps consist of the annual subscription of one guinea and the cost of the uniform.

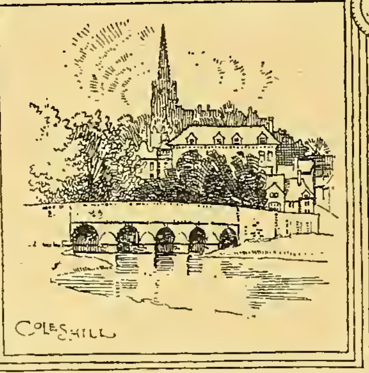
The call upon one's time is not excessive, as the minimum attendance required is one night a week, and those who are deprived of the pleasures of motoring in the ordinary way may be glad to have the opportunity of still continuing to drive, and at the same time of doing useful service for their country.

A New Use for Motor Cycles.

Motor cycles are used in the sunbathed country of South California by men who patrol the orange and lemon districts to protect them against injury from frost. The growers use crude oil burning heaters to warm up the fruit in their groves when the temperature drops to 30° or less during the winter nights, and in order to know when to begin lighting the heaters the growers maintain a squad of motor cyclists to read the thermometers for them.

Covering Twelve Square Miles Every Hour

There are 136 Government thermometers located on telephone poles, trees, and posts, at the roadside in all the lower portions of the valley, and seven motor cycle patrol men, each having about twelve square miles to cover every hour, are deputed to watch some fifteen or twenty thermometers and register their temperatures on a card, and report if there is any tendency towards frost. The motor cycle riders are therefore to a great extent responsible for the safety of the fruit crops, worth nearly 5,000,000 dollars a year.



Artificial Limbs.

Five more centres for the repair and renewal of the artificial limbs of soldiers are to be opened shortly.

The Canadian R.F.C.

Members of the Canadian Royal Flying Corps in Toronto are proving themselves to be enthusiastic riders of motor cycles in winter, as they use no fewer than fifty motor bicycles and sidecars, which are in daily use, in spite of deep snow and furious storms. In that part of the world they are setting the fashion as regards winter riding costumes. With brown leather jackets, helmets, leggings, and fur-trimmed goggles they present a striking appearance. The military riders, we learn, are proving the value of the motor cycle for winter work. They go everywhere and through everything without a hitch, and have opened the eyes of a number of people to the utility of the motor cycle.

Pte P. L. Bassett, M.T.,A.S.C., taken a prisoner at Cambrai. He was a member of the Doncaster Motor Cycle Club, and a frequent competitor in the trials of that district.

Special Features

A GLOSSARY OF FLYING TERMS.
BRITISH AND AMERICAN MACHINES.
SKETCHES IN PRE-WAR FRANCE.

President of Wolverhampton Motor Cycle Club and War Bonds.

When the Tank was at Wolverhampton last week, Mr. Alfred Bird, M.P., president of the Wolverhampton Motor Cycle Club, took up £30,000 of War Bonds.

Big Figures.

In these days of big figures it may be interesting to learn that the fall of rain for 1917 in the United Kingdom was 2% less than usual. This 2% represents 7,000,000,000 tons.

An Ex-King and his Petrol.

Rumour has it that trouble is afoot in Zurich because Tino, late of Greece, has fourteen cars which he can keep in continuous service, although other residents of Zurich have no petrol at all for use in their cars.

The Question of Reinstatement.

The National Alliance of Employers and Employed last week discussed the question of the reinstatement of men serving with the Forces. A constructive scheme will be placed before the Government.

Coventry Branch of the I.A.E.

The Graduates' Section (Coventry Branch) of the Institution of Automobile Engineers are having a paper read to them by Mr. A. G. Perdrell on "Motor Cycles" next Tuesday (the 19th inst.) at the King's Head Hotel, Coventry. The chair will be taken at 7.45 p.m. by Mr. W. J. Tennant.

The Tank at Coventry.

On Monday last the travelling Tank made its appearance in Coventry, to the accompaniment of a brass band. Peculiar interest is attached to the event, inasmuch as the first men for the Motor Machine Gun Section were recruited in Coventry by *The Motor Cycle*, and it was from this section that the crews for the first Tanks were obtained.

The Motor Cycle and the Missionary.

Motor cycles are used by missionaries in various outlandish parts of the world. One of our most faithful readers was an American missionary who worked for many years in Southern India, and was a keen Triumph enthusiast.

We have lately heard of a missionary who has been using a Harley-Davidson in Korea, and he reports that numerous fellow-missionaries are using similar machines. He is now using a three-speed Powerplus Indian. He writes: "The motor cycle has come among us to take its place with us in serving the poor heathen in this wild part of the globe."

ails Lost at Sea.

The Postmaster-General announces the ss at sea through enemy action of parcel ails for Malta (Civil Post Office, Fleet, d hospitals), containing parcels posted ring the month of December; and also mails from the Egyptian Expedi- onary Force containing letters posted etween January 21st and 26th approxi- ately.

eronautical Training.

The Motor Training Institute, Ltd., 10, eddon Street, Regent Street, London, .1—a motor school appointed by the oyal Automobile Club—is now prepared give courses of lessons in aeronautical struction. Doubtless numerous readers *The Motor Cycle* who are taking an terest in aviation will be glad to have articulars, which will be sent to them application by the Motor Training stitute, Ltd.

ngineers and Oil.

At a meeting of the National Motor yclists' Fuel Union on February 4th, the Imperial Hotel, Birmingham, the ollowing resolution was unanimously dopted: "That this representative meet- g, comprising delegate members of the ational Motor Cyclists' Fuel Union, nd consisting of engineers who are fore- en, shop stewards, and leading hands aero engine, motor shipbuilding, and ther engineering factories engaged on ar work, pledges itself to do all pos- ible by personal effort to economise in e consumption of petrol, paraffin, bricating oils, grease, and other im- orted petroleum products, in order that ore shipping space may be available bring food into the country, and the uel provided to distribute it by road otors."

Motor Transport Volunteers.

Owing to the growth of the work of the Motor Transport Volunteers, who convey leave troops across London, larger headquarters have been secured, and are now in use, at 225, Oxford Street, W.1.

The Engineering Standards Committee.

In the article on standardisation in the *Board of Trade Journal* for February 7th, to which reference is made elsewhere in this issue, there are several complimentary remarks made to the Engineering Standards Committee.

Petrol on Irish Coast.

An Irish correspondent asks us—apparently in all seriousness—whether we recommend him to use petrol or paraffin for running his motor cycle. Petrol is available at 1s. 6d.-3s. a gallon, and is continually being washed up on the shore, but paraffin, he says, comes out on an average somewhat cheaper!

Petrol for Soldiers.

There appeared in the issue of January 31st a letter regarding the granting of petrol permits to men of H.M. Forces while on leave or convalescent. This dealt with the case of an applicant who, though he did not own a motor bicycle himself, was joint owner of one with his brother, and so was unable to get a permit granted to him because the regulations stipulate that the applicant must be the registered owner of a motor vehicle. The matter has been brought before the Petrol Controller's Department, and we are informed that licences will now be granted to a member of H.M. Forces while on short leave from the fronts, or convalescent, provided there is a motor vehicle available for them owned by a member of the household or by a very near relative.

"The Motor Cycle" Roll of Honour.

At the present date *The Motor Cycle* Roll of Honour stands as follows:

Sec.-Lt. Geoffrey Smith (Editor). Equipment Officer, R.F.C.; Engine Department, Air Board.

Capt. H. D. Teage. Equipment Officer, R.F.C.; engaged in technical work, and retained at Farnborough.

Lt. Maurice Sampson (afterwards Editor of *The Light Car*). R.F.C.; in charge of group of aeroplane manufacturers.

Sec.-Lt. B. Alan Hill. R.F.C.; served with the British Red Cross, was discharged; later took up a commission as Equipment Officer, R.F.C.; holder of Mons Medal.

Sec.-Lt. N. C. Barnes. R.A.; at the outbreak of war was a member of the Warwickshire Yeomanry.

C. F. Hayward. R.N.A.S.; served with Service de Santé Militaire (French Red Cross).

Pte. S. A. M. Witham. A.S.C.; quartered at base in France; served as despatch rider and was wounded.

Cpl. T. W. Parker. A.S.C., M.T., serving with Egyptian Expeditionary Force.

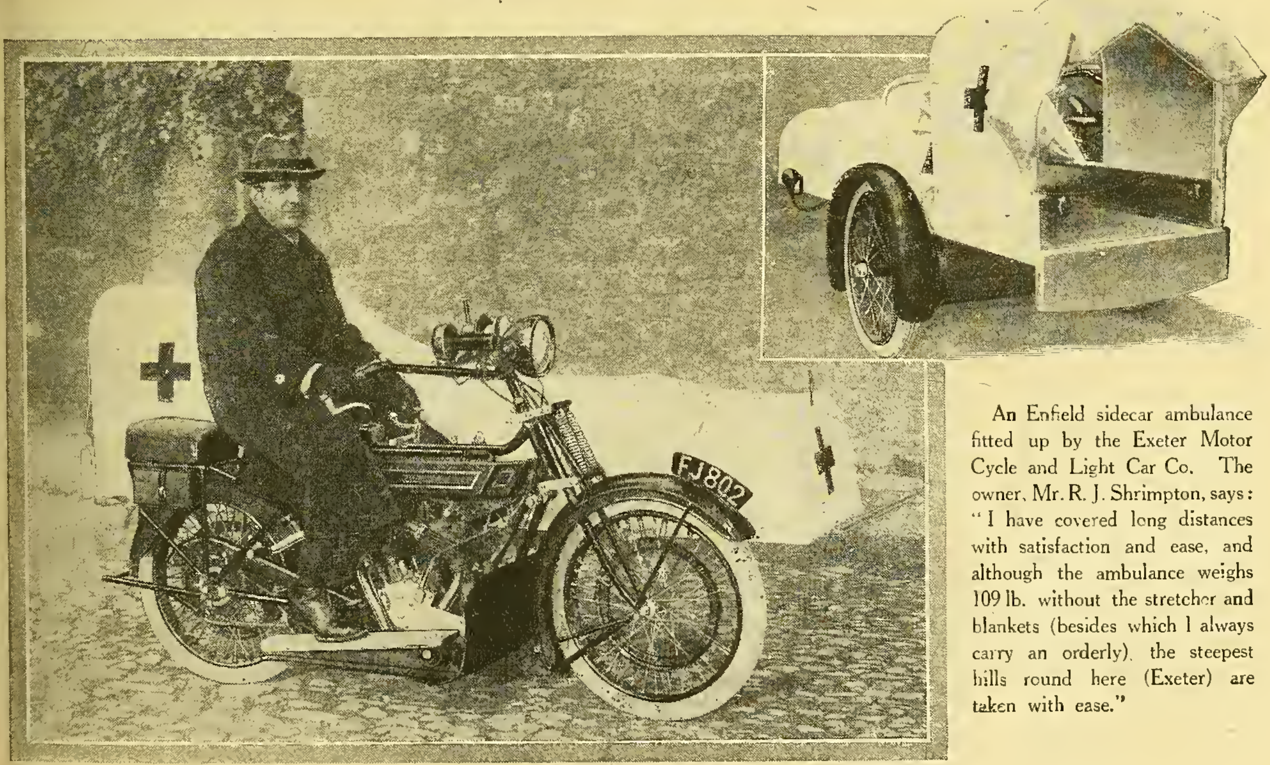
Gnr. G. Beresford. Wounded in France.

H. M. Batten. Service de Santé Militaire (French Red Cross).

All the above are of the Editorial Staff.

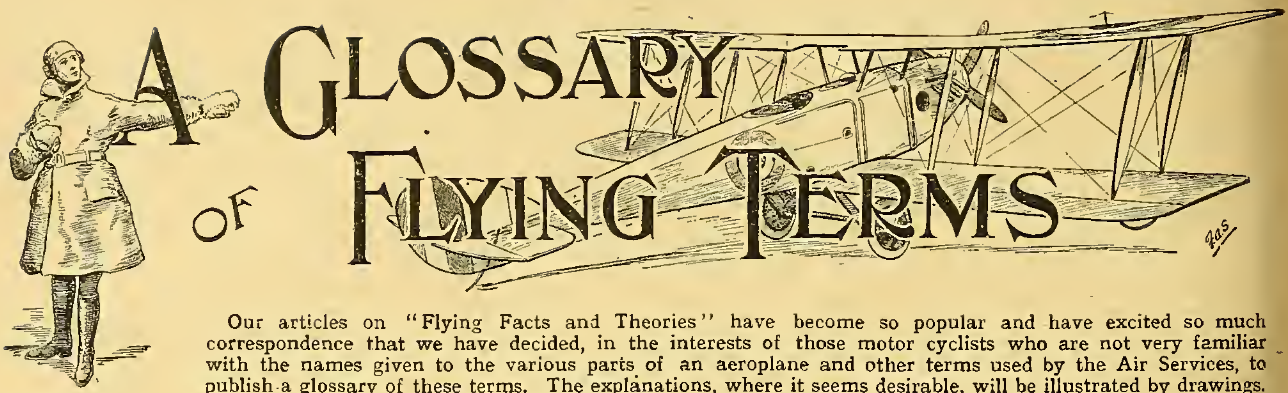
Capt. H. B. Elliot (Advertising Staff): Tanks Corps.

Maj. A. J. Palmer (Assistant Cashier). Tanks Corps; joined the Motor Machine Gun Corps in 1914.



An Enfield sidecar ambulance fitted up by the Exeter Motor Cycle and Light Car Co. The owner, Mr. R. J. Shrimpton, says: "I have covered long distances with satisfaction and ease, and although the ambulance weighs 109 lb. without the stretcher and blankets (besides which I always carry an orderly), the steepest hills round here (Exeter) are taken with ease."

A GLOSSARY OF FLYING TERMS



Our articles on "Flying Facts and Theories" have become so popular and have excited so much correspondence that we have decided, in the interests of those motor cyclists who are not very familiar with the names given to the various parts of an aeroplane and other terms used by the Air Services, to publish a glossary of these terms. The explanations, where it seems desirable, will be illustrated by drawings.

AERODROME.

Often abbreviated into "'drome": literally means a flying machine or "aerial runner." Is applied to a flying ground, sometimes to indicate the open starting and landing space in the centre, sometimes to cover the hangars, workshops, offices, etc., as well.

AERODYNAMICS.

Literally, the study of aerial forces: the science of mechanical flight, but with special reference to utilising the air for lift and motion.

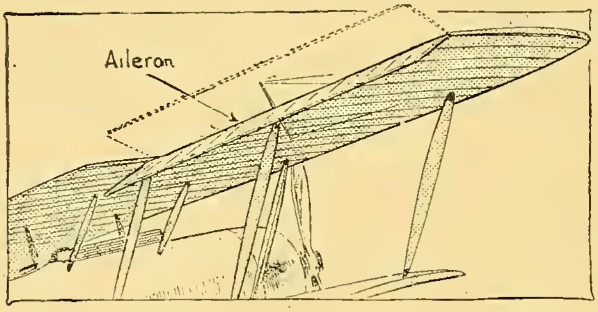


Fig. 1.

AEROFOIL.

Literally, "air leaf." A pedantic term, seldom used except in highly technical works, for the lifting or controlling surfaces of an aeroplane. It implies a curved surface of considerable area, but no great thickness (see fig. 1).

AERONAUTICS.

Literally, the study of sailing in the air: the science of aerial navigation. Aeronautics thus includes such subjects as steering a course in flight and the perfection of compasses, which do not properly come under aerodynamics.

AEROPLANE.

A heavier-than-air flying machine; literally, an "air-surface."

AEROSTAT.

A lighter-than-air flying machine: an airship: a gasbag.

AILERON.

The hinged flaps fitted to the rear edges of the wing-tips of most aeroplanes for purposes of lateral control—*i.e.*, of banking the machine for a turn, of making it sideslip, and of keeping it on a level keel (fig. 1).

AIR POCKET.

Otherwise called a remou, or more commonly described by its effects and simply called a "bump." Patches of rarefied air and downward wind currents may cause a machine to "bump," or suddenly lose altitude whilst flying. Such a "bump" may affect the entire machine, or one wing only: an upward current under one wing will feel just the same as a downward current above the other wing. It is not possible for the pilot to distinguish between these phenomena, except by deduction from the natural objects which cause them; for example, when a machine crosses the coastline on a hot day, hot air will radiate from the sandy beach much faster than from the sea. A pilot flying out to sea at right angles to the beach would "bump" out of the fast upward current from the sand, down into the slow upward current from the water, and might speak (inaccurately) of having fallen into an "air pocket." A pilot flying along the coastline might get one wing of his machine into the air rising off quickly from the sand, and the other wing into air rising slowly from the water: he would then get a sideway bump towards the sea, etc.

AIR SCREW.

The correct general term for the propellers of both tractor and pusher machine (*q.v.*), only used by pedants and in technical works. In the Services the abbreviation "prop." is invariably used for both types of air screw, though, strictly speaking, a propeller is the air screw of a pusher machine.

ALTIMETER.

An instrument employed for measuring height. A common type takes the form of a flexible vacuum box, the lid of which responds to the varying pressure of the atmosphere at different altitudes. The movements of the lid are magnified by a system of linked levers, which operate a needle swinging over a dial calibrated in hundreds and thousands of feet.

ANGLE OF INCIDENCE.

Before the significance of the angle of "incidence," or of "attack," as it is sometimes called, can be grasped, it is necessary to understand how an aeroplane obtains lifting power from its planes. If a sheet of notepaper be held in the face of a mild breeze, three different positions are of interest (fig. 2):

(A) Horizontal, with its surface parallel to the breeze. If it is held exactly in this position, the breeze will not affect the paper visibly. The thin edge of the paper will not offer any perceptible resistance to the wind: in flight parlance, it will not cause any "drift." Neither will the paper tend to rise into the air, for the breeze is not directed against its under surface, and so cannot impart any "lift" to the paper.

(B) Vertical, with its surface at right angles to the wind. In this position, the wind will tend to blow the paper straight backwards, or even to tear it in half, if it is strongly held. The paper is now offering the maximum resistance or "drift." It has no tendency to "lift" or flutter upwards, because there is no upward pressure on any part of its surface.

(C) Tilted towards the wind, with its front edge above the rear edge. In this position the paper tends to rise in a back-

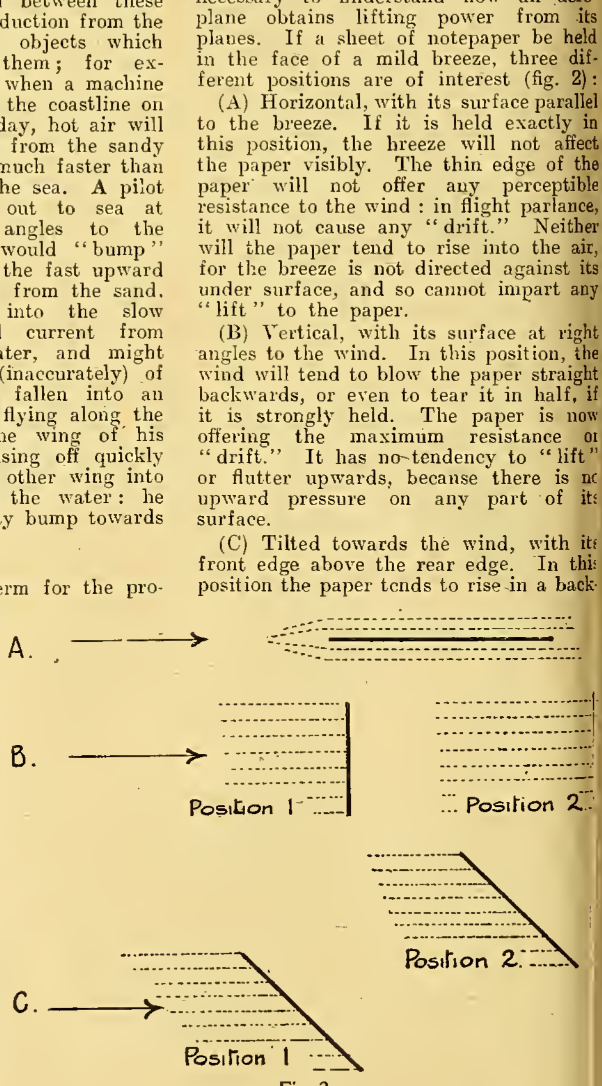

Fig 2.

A Glossary of Flying Terms —

ward direction. The breeze is striking ts under surface, and so imparts "lift": at the same time the paper is offering resistance to the progress of the wind.

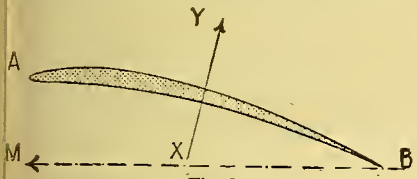

Fig. 3.

Positions A and B are not used in flying, even with the curved or cambered surfaces employed on aeroplanes. The lifting and controlling surfaces are always driven into the air at an inclined angle, as in C: and this angle is the angle of attack or incidence, which can now receive closer definition.

By Newton's law of motion, an equal and opposite reaction is opposed to every action. Thus, if we drive the aerofoil or surface AB in fig. 3 through the air in the direction shown, we provoke an equal and opposite reaction. It is this reaction on which we depend for flight, and its direction is indicated by the line XY. The above experiments with a piece of notepaper show that this "reaction" is the combined result of two different forces, or of forces acting in two different directions: the paper, when held stationary against the wind in position C, fig. 2, tended

(i.) To rise or "lift"; and
(ii.) To blow backwards or "drift."

When the curved surfaces of an aeroplane are thrust against a mass of air at, say, 100 m.p.h. by a powerful engine operating a propeller, these two forces, or two "components of the reaction," are brought into play. They are shown in fig. 4 with their respective directions. "Lift," the vertical part of the reaction, operates vertically; "drift," the horizontal part of the reaction, operates horizontally. Lift tends to raise the aeroplane off the ground; drift tends to blow the aeroplane backwards. No matter at what angle between 0° and 90° we drive the plane AB, we shall provoke a reaction, consisting partly of "lift" and partly of "drift." If AB were flat and had no thickness, there would be no reaction at all at an angle of incidence of 0°: and at 90° the reaction would consist wholly of "drift." As AB happens to be curved, it is less easy to discover the angles at which it is absolutely ineffective for flying purposes. Nevertheless, the experiments with a sheet of notepaper will show that the "drift" is less with the paper nearly horizontal, or at a small "angle of incidence," and that the "lift" is best when the paper is tilted backwards rather steeply. This is very annoying, as the designing of an efficient aeroplane clearly depends on our securing the maximum of lift and the minimum of drift: a high angle gives one, and a small angle gives the other. Our plane can only be set at one fixed angle, until somebody invents planes which can be adjusted by the pilot whilst he is flying. So we shall have to compromise and select an angle for our plane which gives a good ratio of lift to drift.

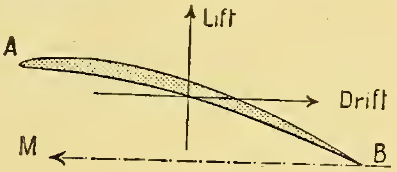

Fig. 4.

We shall wish to talk over our angle of incidence with other designers, so we must settle upon a standard way of measuring it. Every schoolboy knows you draw an angle by inclining two straight lines towards each other, and measure the arc between them with a protractor. The direction of motion will do very nicely for the base line of our angle, but the plane itself is a curved line: how can we find the top line by which to draw a measurable angle? For rule of thumb work in hangars, where this angle has to be adjusted by setting the bracing wires, we can draw a string from the front edge of the plane to the rear edge (this line is the "chord" of a plane), or lay a straight-edge along the chord. This is not quite accurate enough for a scientist. Some planes are so curiously shaped that they will fly when the chord comes below the direction of motion, instead of above it, so giving what is called a "negative" angle of incidence.

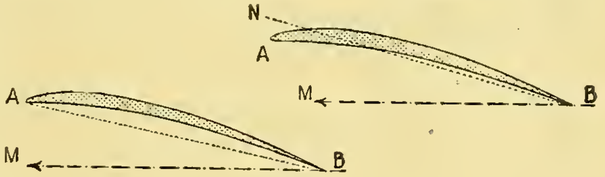

Fig. 5.

The scientist measures the angle of incidence between the direction of motion as the base line, and the "neutral lift line" as his upper line. The neutral lift line can only be calculated: it cannot be found in any given plane by rule of thumb. This is what it is. If the plane AB is lowered down towards the line M—the direction of motion—it must eventually be so flattened out that it will give no lift, and cannot fly. When the position in which it ceases to lift is found, draw a horizontal line through the plane from the trailing or rear edge B. This line is the neutral lift line. When the plane AB is mounted on an aeroplane, its angle of incidence is the angle between the direction of motion and the neutral lift line. Thus in fig. 5 the angle ABM is the riggers' angle of incidence, used in the hangars; and the angle MBN is the designer's angle of incidence, used in the laboratory, the wind tunnel, and the drawing office.

In the hangar, the riggers set the angle of incidence by the makers' instructions, which may take some such form as this. The aeroplane is propped up until a spirit level placed on the engine bearers centres its bubble precisely. A long straight-edge is then placed under each plane in turn, with its rear tip touching a stated part of the plane—*e.g.*, the centre of the rear spar. This straight-edge is levelled horizontally with a spirit level. The distance from the front edge of the plane to the straight-edge is measured in inches by a plumb-line, and must be set to, say, 6in.

A designer arranges for a certain angle of incidence, which the planes will assume in the position of horizontal flight. The pilot varies this angle in flight by the use of his elevators. For example, the angle for horizontal flight may be 3° or 4°; in climbing, the elevators will increase the angle to 7° or 8°; when the pilot deliberately "stalls" the machine to make a landing, the angle may reach 15°.

* * *

STANDARDISATION.

IS IT REALLY COMING AT LAST?

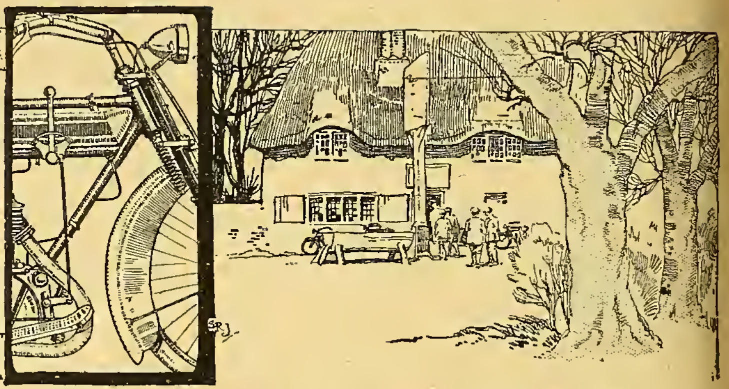
THE *Board of Trade Journal* for February 7th contains some lengthy and interesting remarks on the absorbing topic of standardisation. The way in which certain sections of the community are awaking to the full significance and possibilities of standardisation is almost amusing as well as eminently gratifying. In this issue of the *Journal* the question is dealt with as it concerns ships and marine engines, locomotives, machine tools, electrical trades, iron and steel trades, and the textile industries.

It is pointed out that America especially has benefited from this development of standardisation wherever possible, and as a specific instance is quoted the American capture of a large share of the machine tool trade, especially in milling and grinding machines and automatic lathes, as a result of carefully standardised manufacturing methods.

It is interesting to note that Swiss watches are coupled with American motors, agricultural implements, typewriters, and telephone appliances as further examples of what has been done by the adoption of standardisation methods.

It is clearly pointed out in the article that foreign competitors have only attained their high degree of standardisation by close co-operation between the various manufacturers in specified trades, and that if our manufacturers wish to compete with the foreigner they must first decide on a scheme of close co-operation amongst themselves. There is no harm in repeating once again that the key to the whole situation is quantity production on as large a scale as possible.

AMERICAN AND BRITISH MOTOR CYCLES



A Criticism of "Chinook's" Article, and a Defence of American Practice.

I SHOULD like to try and answer "Chinook's" drastic article on American and British machines, although I do not claim to be a writer, but it would not be right to let such statements pass without disputing them to some extent, and to me it appears, with all due respect to "Chinook" as a writer and rider, that he has not had a very wide experience of American machines, either on the road or at the bench.

I am rather surprised that "Chinook" should write in such, shall I call it sarcastic, manner, and shall I add that I think he would change some of his views and arguments were he to be less biassed and get more hard experience, because experience does teach? First, I ought to explain that I have had sixteen years in *the* trade (not kindred trades), and may be classed, I think, as an enthusiast. This period covers berths as charge hand in large garage, proprietor of large motor cycle business, building the much-run-down "local-made" machine, with a fair sprinkling of racing and competition work. This is not mentioned out of any spirit of boastfulness, but just to show that I have a knowledge of British machines of all types, makes, and powers. During this time my own machines have been many, and to-day I have a Norton, Rudge, and two 1,100 c.c. American twins of well-known make, and it is from experience with these many and varied makes that I base my opinions. Moreover, bench work on the best English and American practice is very interesting, and greatly helps one to make comparisons.

Accessibility.

"Chinook" makes a very one-sided claim when he compares a 500 c.c. flat twin with a big V twin of any country's origin, and, in fairness to all concerned, the best and most representative makes of both countries under discussion ought to be used, and not a star up-to-date masterpiece of our Homeland against, perhaps, some little known and perhaps out-of-date production from across the pond. Some of our lesser-known makes over here will not stand much limelight and criticism (does "Chinook" know of a *British* flat twin where, if the magneto has to be taken off, the engine complete must be removed? I do only too well); and I will undertake any time to take off the magneto of either of my American twins whilst he performs the same operation on the British flat twin. We must also bear in mind that, after all, the accessibility of the magneto is not of such vital importance; by that I mean there are far more vulnerable points on a machine which require attention oftener than the very reliable type of magneto which we are favoured with to-day. In pointing out some of these vulnerable points, I shall try to show that in many cases they receive more and better attention from the American manufacturer than the majority of our home producers.

As a set off to "Chinook's" struggle, covering *two* hours, may I ask him if ever he has tried to remove a sprocket, fixed in the orthodox English manner, *i.e.*, screwed, after it has done a season under power, and then the American type, where the sprocket can usually be pulled off the splinings of the hub or sleeve-shaft after simply undoing a lock ring? That is, of course, only one small detail, but an important one in accessibility.

Cleaning the Engine.

As to engines, well, personally, when used to it, I would far rather remove the engine bodily from the frame to clean it out, or have detachable heads, than struggle on the floor with the usual type of English big twin, and I can complete the operation more quickly. Perhaps, however, this is a matter of opinion, so we will leave it at that. There are also many other little points which compare very favourably with the flat twin instance, and I should like to show "Chinook" that against his two hours' struggle I will give him the magneto from either of my machines in less than a quarter of an hour, and that is as good as, and better than, perhaps some English twins—flat and V—of which I happen to know. Compare the Rudge single-cylinder magneto drive with strap fixing, ensuring very quick and easy detachability, and then note how this firm had to depart from its standard and come to the common method of chain drive, with the usual magneto position and fixing on its 1,000 c.c. twin, again proving, after all, that there are not a great number of different ways of doing this job. The writer, in the 1910 T.T. race, rode a machine he designed and built, in which the magneto was detachable in thirty seconds, but it did not stand a rider in any good stead, simply because it was not by any means an every day occurrence to take off the magneto, so I think that "Chinook's" ideas of comparing such points as these to run down a machine are very shallow, and ought to have been left out.

Engine Balance.

Then I come to engine balance, periods, and smooth running. I think "Chinook's" own confession that the Americans turn out a far smoother running and silent engine, and have beaten us on this point, is sufficient answer to his own criticism, when we reckon that firms who will pay much attention to other details will not make sure that their engines are as well balanced as possible. If he will closely examine the construction of one of these well-known power units he will see that things have been thought out in such a long and level-headed manner that the bad balance and most "appalling period" which are so obvious in many English engines to-day are non-existent as far as mechanical design can make them; and it does not need a very brilliant engineer to see this. My personal experience at the bench confirms my opinion that the average American engine, inside and outside, is as good an engineering proposition as any of ours, and my road tests have never shown me that their engines suffer from a period, or lack of durability.

What, I ask, is the matter with *any* American machine which is *selling* in this country? One seldom sees an American machine running other than smoothly, silently, and silkily, without that shake-to-pieces-in-neutral style so common on most of our machines, due perhaps in a large measure to poo carburetters, combined with many othe factors in design, some so very plain t see in many (too many, alas!) Englis engines. I notice that "Chinook" neve mentions such things—details to him perhaps, but boons to hundreds of riders as mechanical lubrication and air release automatic carburation, splendid an durable design of all engine details bearings, pistons, and general interna parts, timing gears (usually no rattle) valve ports, pipe fixings, and othe details too numerous to mention.

Fittings.

Then he refers to "fittings and fittings. Amongst these he classes the brake—tha all important fitting—which he admits usually a good job, and works well, so think his reference to holding togethe until permanently rusted to the fram may be crossed off as simply too ridiculo to answer. Statements like these mu

American and British Motor Cycles.—

undoubtedly lead a certain class of the British public to sympathise with us poor mortals who have unfortunately been saddled with what he would have us believe are glorified scrapheaps in return for our hard-earned coin.

To his reference about twist grip control and the three positions it gives—full, half, and shut—I am sure he must either be trying to be sarcastic or else he has never really had much experience with a movement which, personally, I prefer to all tap-twiddling, and I think this would be better answered by riders who have changed from one to the other; they surely will give an unbiassed opinion. I know which I like best; but, of course, I had to try it to be convinced, and now I am tap "twiddling" all the day—it is my bread and butter.

Split Pins.

Where he finds his sixty split pins I am at a loss to know; but, after all, are they such a tremendous disadvantage as he says, and would not some English machines (with a period) already fitted with pins do better with a few more round about? Both my machines together cannot total sixty pins; the nuts, studs, and pins are a good job. We might also make comparisons in frame design and construction, and we must remember that the Americans have had successful spring frames for a good few years now, and have left off the use of castings for lugs (a big cause of trouble in a 550 c.c. well-known W.D. single) and used stampings and pressings whenever possible, and have discarded the usual common type of push cycle handle-bars and fixings by clip and bolt, which we still strongly adhere to. Fork design and lubrication of moving parts by sensible oilers have been features for years.

Other Points of Design.

Then tanks and tank fixing, gear boxes and heavy duty gears, clutch design and methods of operating, interlocking of gears and dual control, good methods of engine fixing, large wheels and tyres, big ground clearance, sensible design of hubs and spindles, and other points of general completeness, show attention to details which leave "lawn mower and agricultural machinery," and many British motor cycle designs, far behind.

I will not go into any really vile faults of some British designs, but amongst others does "Chinook" know of a "Big Four" where it is necessary to drive out the gudgeon pin, after slightly lifting the cylinder ere the cylinder can be removed; also an English twin and sidecar where the gear case and chain cover cannot be removed until the sidecar is detached owing to one of the arms fouling; some machines where there is great difficulty in getting the rear wheel out without taking off the back stand, and in some cases the guard; a well-known sidecar "Six" where it is practically impossible to remove the driving sprocket from the gear sleeve shaft by any ordinary methods; and the English engine where the small timing pinion is screwed on the crankshaft without any provision for removal outside the works—these instances being only a few random ones found on some of our best-known makes.

One never sees the Americans fit the obsolete type of front rim brake or so much cable work to the rear brakes. And has "Chinook" ever seen the same average number of frame breakages and fractures that are so noticeable on some of our frames—this in spite of his reference to drilling back stays, etc.?

No, I do not think "Chinook" has been broad-minded enough in his criticisms, and some of his faults and statements are, I am sure it will be admitted, in many cases imaginary. I am not out to pull the English machine to pieces unmercifully, but I do maintain that we could with advantage take a few tips and improve our machines to compete with the world.

Advice to British Makers.

One has only to follow up some of the Overseas letters in *The Motor Cycle* at times to find that my ideas are to a certain extent fairly general in the Colonies. Design and methods of service—*i.e.*, treatment of customers and supply of parts which *do* fit—go a long way to assure the Americans a big prestige for many years to come, unless we are very quick to grasp facts, and do not argue with each other in a poor sarcastic way over obvious things whilst Uncle Sam is taking our trade. This prestige will never be attained whilst we take such narrow-minded views and talk as though all foreign machines were old iron.

I should like to see some enterprising British manufacturer embody a few of the American ideas, and then we should certainly see which way the wind blows, for the public are the best indicators of that, after all. Like "Chinook," I, too, am an Englishman, at present in khaki, and still on a motor cycle job, and I could add a bit more on W.D. machines, but "nuff sed." I am sticking to my Yanks until——? and when we do get the enterprise (and competition *will* be keen after the war), then I shall certainly come back to a British machine. Of course I admit that our singles beat easily the American efforts in this line, and my Rudge and Norton leave me satisfied in that respect. But because British manufacturers have specialised in the single we must not forget there is such a thing as a twin, and twins are mainly our present concern.

Summary.

I hope some riders—not the type referred to as resorting to paper experience, but practical road men with average mechanical riding ability—may see fit to express their opinions in your pages. In conclusion, we must not forget that the Americans work against a $33\frac{1}{3}\%$ disadvantage in this country, and if that were removed (I am not entering into politics), we should (to use army parlance) have to "put a jerk in it" to mark time with our friends and Allies across the pond.

Of course, be it noted, I do not make such sweeping statements against the typical British machines; we are well in the running, and turn out some fine productions (also otherwise), yet I maintain that our best would be improved by the addition of a few points from America, in the same way that theirs would be improved by some of our ideas. Yet again I add that "Chinook" was far too hard and biassed. Competition, all will admit, helps to improve the breed, and I long to see that improvement come, and put it forward as my excuse for my poor efforts as a writer. In the meantime I am a satisfied rider of American machines, and shall remain so until such times as I have mentioned, and then I shall be glad to possess an "after the war" British production which will be a standing example of top-hole engineering to the world. MOVEO.

REJOINDER BY "CHINOOK."

In reply to my various critics, let me say that I certainly did not wish to be unfair to American machines. I must confess, however, to feeling a sort of fed-up-ness at having had the merits of the U.S. production held up as a model of desirability by some scores of correspondents, while there seem so few journalists who thought it worth while to come out with what they consider to be the plain unvarnished truth. The journalist may not have the workshop experience of the repairer, but, at any rate, most new models, both American and British, pass through his hands, so that his comparisons should be of some little value; also, if he is up to his job, his judgment is not merely superficial.

As regards my experience of U.S.A. machines, I may say that for eight years I lived in the midst of them, so can probably claim rather wider knowledge than my critics, whose experiences are clearly limited to the one or two makes which reach this country bearing the hall-mark of America's best factories. Correspondents are fond of comparing America's two or three best machines with the various dumped lot of British mounts that find their way to obscure regions Overseas, which is manifestly unfair. Let us take the Triumph, Lea-Francis, Sunbeam, B.S.A., P. and M., Norton, A.J.S., and Enfield—eight of our best-known makes—and see if we can find eight Americans that can in any way compare with them on the points raised.

I repeat that there are some features in every-day American design and finish which no British manufacturer of repute would tolerate for a couple of hours. There may be one or two Americans that are as good as Britain's best as regards their power units, but even these are inferior to the average run of well-made British machines on more points than they are superior. Moreover, the power unit is not *everything* in any machine.

Let us, at any rate, be honourable with ourselves, and not pretend, above all things, that we believe American design to permit of the same degree of accessibility as ordinary British practice. Such a contention is absolutely ridiculous. One of the best (electrically equipped) Americans of to-day took three skilled engineers of my acquaintance fifteen men-hours to decarbonise! If I possessed a Britisher that I could not decarbonise single-handed in an afternoon's work, the readers of *The Motor Cycle* would hear about it. CHINOOK.

Export of Motor Cycles from 1906 to 1917.

The Million Mark passed Twice during the last Four Years.

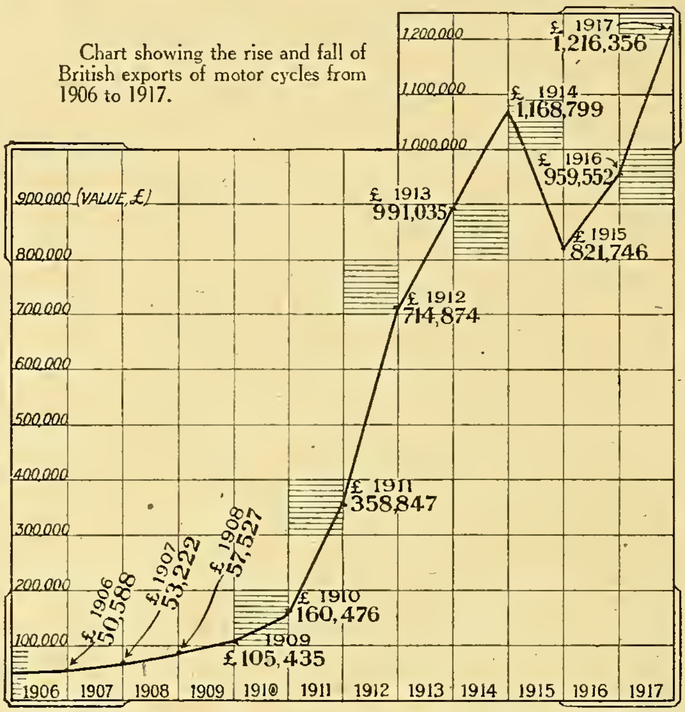


Chart showing the rise and fall of British exports of motor cycles from 1906 to 1917.

THE chart reproduced herewith shows how the British motor cycle industry has progressed since 1906. Last year is given as being the biggest export year on record, and it was stated as such in *The Motor Cycle* of Jan. 31st. There is a word of explanation needed, however, on this point. The figures for 1914, viz., £1,168,799, were taken from the Board of Trade returns for December, 1914. Since quoting them we find that the following year (December, 1915) the Board of Trade altered the figures to £1,305,250. If the latter are correct then 1914 is the record year. The rise from £160,476 in 1910 to £1,168,799 in 1914 is an increase of 700% in four years. It would be well to ask those who are continually nagging at our manufacturers on their alleged indifference to Overseas trade whether their plaint is justified. Few industries can show a better record, but even so we firmly believe that with increased energy and a totally revised method of distribution, and above all a revision of the price and stocking of spare parts in the various motor cycling centres Overseas, these figures can be tremendously increased. No better proof can be shown than the figures for last year. If such a total can be amassed under unfavourable circumstances, what may we expect in normal times?

* * *

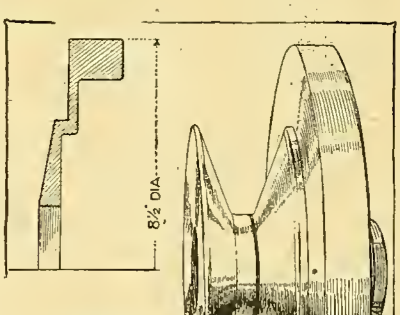
Outside Flywheel and Adjustable Pulley.

An Idea which will Appeal to Owners of Low-powered Sidecars.

MOST riders of machines fitted with outside flywheels and direct drive to the rear belt rim have felt the need for an adjustable pulley, and have perhaps gone so far as to say unkind things about outside flywheels that have prevented the use of this other useful accessory. Similarly many riders of standard machines fitted with inside flywheels and adjustable pulley all complete long for an extra flywheel to give a rather better torque when the last ounce of power is required from the engine.

An invention recently provisionally patented by Lieut. G. S. Burney, R.E., provides for the fitting of both the above suggested desiderata, and is simplicity itself in its application. It consists of an adjustable pulley, the outside—removable—flange of which is made of increased diameter to form the web of a flywheel, and is provided with an enlarged periphery or rim to increase the flywheel effect.

The locking and moving of the movable flange are recommended to be carried out on the well-known Triumph principle, and, of course, the size of the fitment depends entirely on the machine for which it is intended. Presumably the inventor intends to make it to fit any make of machine provided sufficient market is guaranteed, while, of course, a standard pattern could easily be put on the market, which would be made so that it could be easily adapted by a competent mechanic to fit any individual machine.



A provisionally patented arrangement which enables an extra outside flywheel combining an adjustable pulley to be fitted to existing machines.

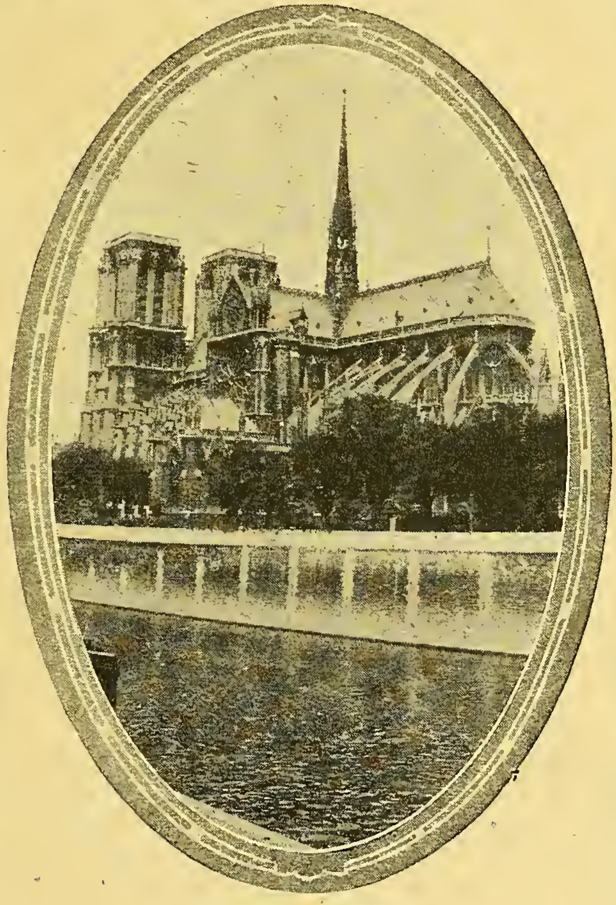
The idea is certainly full of promise, and should prove a very useful addition to many a 3½ h.p. saddled with a sidecar.

The British Committee of the French Red Cross have just heard of the further award of decorations to a number of their volunteer motor ambulance drivers serving in one of their convoys in the vicinity of Verdun. The names of the drivers so honoured are Mr. A. A. Hannay and the Hon. C. Hill-Trevor, Croix de Guerre with silver star; Messrs. J. Bower, W. D. Linsell, and E. Hartley Hacking, Croix de Guerre with bronze star.

LITTLE SKETCHES IN PRE-WAR FRANCE.

I.—A Jaunt from Dieppe to Paris *viâ* Gisors and Asnières.

THREE in the morning, and a dim light on the cobbled streets of Dieppe as we wheel our little Douglases down the quay. My friend was taking a well-earned holiday from his newspaper work in America, and we had decided on a run to Paris, stopping there ten days or so, and return by Rouen. After a glance at the C.T.C. "Continental Road Book" (an invaluable handbook, and one to be remembered against happier times), we threaded our way out of the town by the Place de la Barre, the silent street giving back the contented purr of two well-tuned engines. A stiffish rise, and then we were faced by one of those blade-straight roads such as we do not know over here, bordered by tall poplars stretching into infinity, and gloriously inviting for a "blind." Too cold this morning, though, as yet, and we confined ourselves to purring along at a modest twenty-five. The tall trees drip with the moisture of the night, and the sun, struggling up sleepily behind a bank of dark cloud, reveals the far-stretching fields, ablaze with crimson poppies. The road forks, and we stop to consult the unfamiliar-looking signpost, flanked by a wooden crucifix, stained with the weather.



Notre Dame de Paris

The Mad English.

The sun mounts, growing more powerful, and as we speed by we can see peasants, their backs bent with years on years of labour, trudging to work. Feeling thirsty, we stop at a wayside cottage. Someone is about, and we wait for a moment looking at the specklessly neat interior, and the gleam of freshly-scoured copper pans. An old crone, her face incredibly seamed with wrinkles, hobbles out to inspect the two mad English. No, she has no cider, "*mais, il-y-a du boisson.*" We try it, an enormous flagon of the drink of Normandy, rather like a harsh cider, and very gratifying. We pay our twopence, and paddle off. Forges-les-Eaux will do nicely for breakfast: probably seven o'clock will not be too soon in this early-rising country. Riding absently on the left side of the road, we nearly foul a plodding haycart, recovering just in time to return the courteous "Good-day" of the driver. A menacing hiss—for all their fine engineering these vaunted roads are appallingly loose. My friend's front tyre! Only five miles; perhaps we can make it. We do make it just as the feel of the rim on the road is becoming rather too acutely perceptible.

"The Inn of the Candid Friend" invites us, and in response to our enquiry the waiter sets before us huge bowls of milk tinged with coffee, a gargantuan hunk of Gruyère cheese, and two of those enticing crisp loaves that look as though they were bought by linear measure. The puncture can wait till afterwards. Our host's little son comes out to inspect *ces Anglais,* accompanied by a very English-looking fox terrier.

A leisurely meal, and a pipe to follow, while we write picture postcards home, which the obliging postman collects after selling us the stamps. The bill for our breakfast is surprisingly small, "*derisory*" as the French say. The tyre set right, we set out for Gournay, sped on our way by a little knot of onlookers, interested in our compact little steeds.

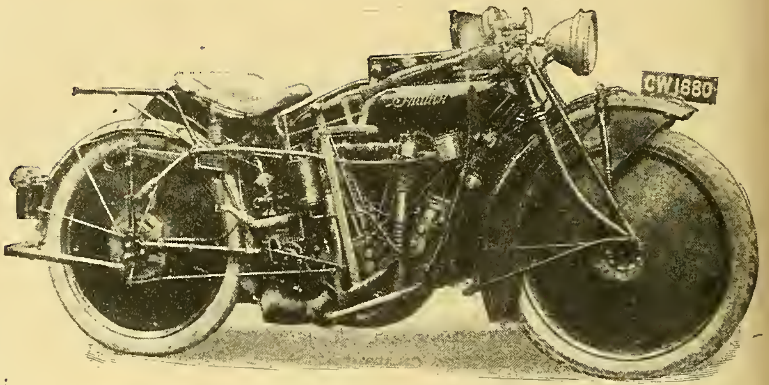
Disaster.

Ten kilometres out of Gournay disaster overtakes us. My friend Pat, who is used to the American twist-grip control, is flung from the saddle while giving a too absorbed attention to the multifarious English levers, which he proceeds to curse "*en gros et en detail,*" seated ruefully in the road. He has suffered no more than a badly-grazed knee, and mounts protestingly in order that we may reach Gisors, where there is reasonable certitude of finding a chemist. A flamboyant sign, "Livery Ones, drink the Water of Miers," in the main street would seem to indicate that we have found what we wanted. I explain to the assistant that my companion has "made bad to the knee," and the wound is thoroughly dressed with peroxide of hydrogen, and tightly bound. A sign "Here one Eats Tripe all the Days" invites to lunch (but not on tripe!), winding up with a Camembert cheese riotous with life—a thought too lively for the unacclimatised. After this all goes well, and we bed down for the night at Asnières—the Kingston of Paris—delightfully tired, and soothed by the vivacious sounds of the gay French street outside, with all Paris to explore on the morrow.

R.H.B.

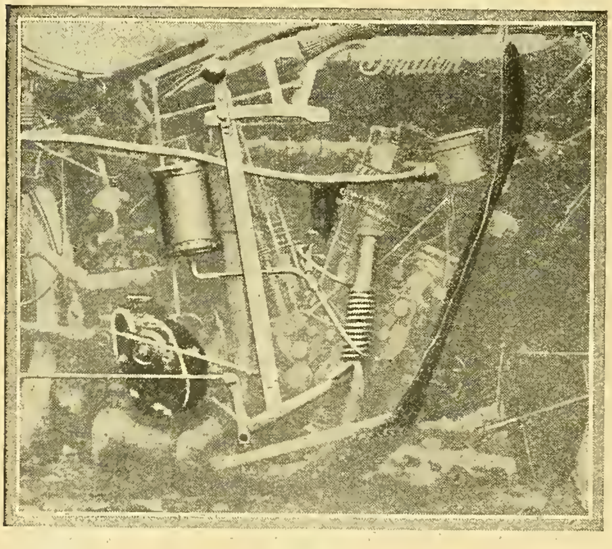
A Motor Cycle with a Steam Injection System.

Various other Refinements go to Make a Specially Well-equipped Outfit.



The Indian outfit owned by E. Brown, Burnley, to which a Mariana steam injection system has been fitted.

FROM time to time the question of mixing steam with the charge of gas crops up in our correspondence, and no doubt there is much to be said in favour of some arrangement which enables this to be done. Mr. E. Brown, who uses a Mariana steam injector on his Indian, has sent us a few notes concerning his experience with such a device, which will interest many who are desirous of obtaining smoother and cooler running of their engines. Mr. Brown says: "The Mariana steam injection system, which I have fitted, consists of a metal water container fitted to the down tube from the saddle, under the bottom of which is fitted a tap to regulate the water supply. When this is turned the water runs through copper pipes round the front exhaust pipe, which convert the water into steam. This is then taken into the carburetter through the bottom air intake. The machine runs far more 'silkily' when this is working, and the engine picks up much better. I have tried various substitutes in the tank with this device working, and after the engine has got warm it runs as well on paraffin and substitutes as on petrol. The petrol consumption is, I think, about three miles to the gallon better since I fitted steam injection.



Detail view of engine showing method of fitting the device. Various other alterations and fittings will be noticed—the position of speedometer, hand-controlled gear lever, and leg shields.

"The photograph also shows the metal leg shields, which allow cold air to impinge on to the cylinders. I have fitted the speedometer to the front down tube instead of on the top tube, and find it is much better to read in this position. A hand control for clutch has been provided, and is conveniently near the gear lever. Round the cylinders I have fitted copper springs for cooling purposes, and think I have obtained a certain amount of improvement from their use.

Sidecar Fittings.

"The machine is fitted throughout with electric lighting, which can be turned on from a switch in the sidecar. This can be done without stopping the machine. I like the Indian very much, and could have disposed of it many times had I wanted. The sidecar, which is fitted with a large bulbous back containing the lighting accumulators, is upholstered in grey leather, and looks very smart. It has windscreen, storm apron, step, cupboard in front, and large adjustable luggage grid. Disc wheels replace the ordinary type, and mud protectors have been arranged for the front wheel. A heavy rubber buffer is fitted in the coil of the front spring to prevent this from rebounding, as the roads in the North are rather rough. I trust these particulars may be of interest to readers of *The Motor Cycle.*"

OUR HARD-WORKED POLICE.

THE other day an employee of the Service Co., Ltd., was driving a customer home in a motor bicycle and sidecar. They were stopped by traffic at Oxford Circus, and while there some other vehicle knocked up against the sidecar combination, causing trifling damage. The policeman on point duty immediately took an interest in the matter, with the result that the Service Co. subsequently had no less than seven visits from the police. So far as can be ascertained all the men were of military age; three or four of them called for exactly the same purpose, namely, to inspect the company's register. The firm has been summoned because the driver of the sidecar had forgotten to renew his driving licence.

The managing director of the company, Mr. G. W. Mann, writes, "My main point, however, is that it seems worth calling some attention to the fact that when there is such a cry about shortage of labour, even our police force should be called upon to make some arrangement by which the time of their staff is not fooled away in this silly manner."

A British Manufacturers' Corporation.

A National Scheme for developing British Export Trade.

IN our issue of February 7th we dealt with the problems involved in reconstruction after the war so far as they are likely to concern the British motor industry. As we stated in that article, the problems to be met in after-the-war trade are extremely numerous, and are not such as are likely to be of simple solution. Sir Charles Mandleberg, of Pendleton, Manchester, has for some time been paying deep consideration to the subject of reconstruction after the war in relation to export trade and the development of British export trade by means of a kind of manufacturers' union.

As Sir Charles points out, post-war taxation is bound to be very high, and we cannot hope to pay all our liabilities out of the profits of home trade; to do so would be tantamount to taking in each other's washing: consequently our export trade takes on an importance even greater than any it has previously possessed, and the best means for developing this export trade is by means of the man on the spot, or export local representative in the territory to be developed.

The main point of Sir Charles's scheme is not so much to replace the representatives of those large manufacturing houses which already have Overseas branches or representatives, but to provide a Corporation of manufacturers and producers, each of whom will subscribe a certain amount annually, and this amount will be devoted to the provision of an Agent-in-charge in any particular territory to be exploited. As Sir Charles states, a Corporation of a thousand members, each subscribing £100 or £200 per annum, would have a fund of from £100,000 to £200,000 per annum, and such a fund would enable the equipment of highly-efficient Overseas depots that have the interests of British trade at heart. In all probability the majority of the members of this association would be business houses to whom export business would be something of a new venture.

The "Agent-in-charge."

The "Agent-in-charge"—one to each territory—would act in the interests of all the members of the Corporation on the lines of the man on the spot now in the direct employ of large individual houses. His duties would really be to represent as a principal each of the members of the Corporation, and he would need, of course, to be a man of high commercial standing and able to discharge with complete satisfaction a position of high authority. He would have behind him the prestige of what might become one of the most powerful and influential exporting organisations in the world, and, on the other hand, this association would regard the Agent-in-charge as its competent representative in the territory in which he was located. The functions of the agent may be summarised as follow:

(1.) To appoint selling agents for the members of the organisations where agents had not been appointed.

(2.) To report on the standing of purchasers. Intimate knowledge at present unavailable could be placed at the disposal of members, and arrangements could be made to send with orders such reports on purchasers' standing.

(3.) To carry out any financial arrangements between producers and purchasers where transactions lay outside ordinary business routine.

(4.) To act in an advisory capacity to members if they needed information as to the best methods of securing further trade.

(5.) To get early information of possible orders and communicate immediately with the selling agents of the manufacturers concerned.

Home Centres.

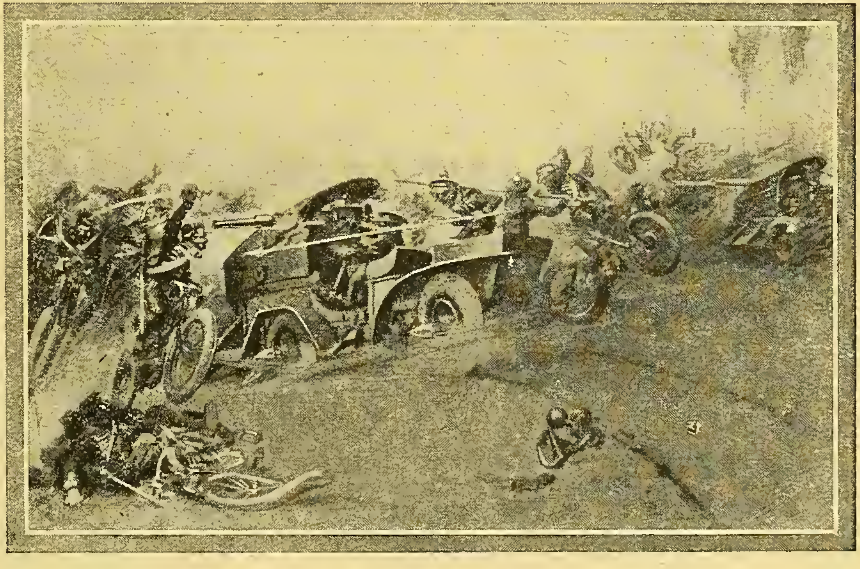
The first step to be taken towards the development of this scheme would be the opening of offices in the chief manufacturing centres in this country, with a small staff in each office. The managers of these home centres would be appointed for their thorough knowledge of the technicalities of the export trade, and would exist for the purpose of advising members of the Corporation of all details connected with the export trade, such as would require to be known before a house, previously limited to home trade, could branch out to the export line.

It is not intended that the Agent-in-charge abroad should be a selling agent, but he would appoint selling agents, when desired by members of the Corporation. Naturally, the Agent-in-charge would be responsible for seeing that no two competing firms were represented by the same selling agent. On the other hand, there would be no objection to non-competing firms having one agent in common, just as they had one Agent-in-charge.

Members whose business is of a highly technical nature might prefer to send out a resident representative of their own to do their selling, in which case it would be an undoubted advantage, and would give them confidence, if their representative could refer to the Agent-in-charge as to the best methods of developing business in that country, and for particulars of firms likely to be useful, and their standing. In an emergency, such as might arise through illness or other cause, the Agent-in-charge would be on the spot to act as he might be instructed. In the case of firms who send out their own travellers, the Agent-in-charge would be available for giving the latest advice and information, as well as to be of other assistance, to travellers on their arrival in his territory.

Legal and Banking Aspects.

It is also hoped that, on account of the high standing that would be maintained by the Agent-in-charge, special legal advantages or assistance would be secured for the members of the Corporation in the foreign territory, and the position of a capable agent on the spot would certainly increase the possibilities and likelihood of satisfactory banking arrangements. The whole matter of banking facilities, as a matter of fact, has been engaging the attention of the British Trade Corporation—a powerful organisation with a capital of ten millions sterling, now incorporated by Royal Charter.



A drawing, published in *Das Schnaufere* (*The Snorter*) in 1903, illustrating the German idea of what modern warfare might be. In those days, when most people were absorbed in improving motor cycles and motor cars for business and pleasure, the Huns were pre-occupied with designs for employing them against neighbouring nations. The sketch represents an attack by motor cycle hussars on a squadron of armoured cars, and is entitled "The Battle of Port Petrolia, A.D. 1925."

LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

THE WOMEN'S LEGION.

Sir,—Will you allow me to draw your attention to a paragraph on page 108 in the issue for January 31st, and to relate my experiences in connection with the same matter?

The paragraph, entitled "Women Drivers for Government Motors," states that these are supplied through the Women's Legion, which organisation "is in urgent need of recruits, who should have some knowledge of driving, but need not be highly skilled."

I own a motor cycle, and have a slight knowledge of cars, and a short while ago, being anxious to take up motoring work, I wrote to the secretary of the Women's Legion, asking to be made a member, and also if I could get any further training or work through the society. I also asked for particulars about the organisation, and what I, as a member, should be expected to do to help it on.

The reply I received was a short letter, advising me to apply to the secretary of the Motor Section, and enclosing a leaflet, which contained little more than a list of the sections and the names of members on the executive committee.

I did as advised, again asking about the society, and stating that I wished to get work as a motor driver. The reply received was even more brief than the first, and after paying a small subscription I was enrolled as a member, and joined Section 2, Motor Transport.

I am still a member of the Women's Legion—though concerning the society I am in total darkness—and it does not seem as easy as it would appear to obtain work through that organisation. (MISS) VIOLET MOORE.

St.-Leonards-on-Sea.

THE DYNAMICS OF BICYCLE LOCOMOTION.

Sir,—The author of the article on this subject in *The Motor Cycle* for January 31st appears to be confusing centrifugal force with the *force peculiar to the bicycle*, which, he considers, gives stability to the machine.

Are we to congratulate him on the discovery of a new force, overlooked by Newton, or is this "force" our despised friend gyroscopic action in another guise?

The motion of a bicycle rounding a circular arc is simple. The machine is simply banked until the resultant moment about the line of road contact of (1) gravity, (2) centrifugal force, and (3) gyroscopic torque due to precession of any rotating parts is zero.

The case of auto-stability, *i.e.*, the capability of the machine to keep a straight course when the handle-bars are untouched, is a very different matter, and a simple, non-mathematical explanation appears to me to be almost impossible.

When a bicycle is subjected to a side load and tends to fall away from such load, the front wheel is subjected to a torque about a longitudinal axis which causes it to rotate (*i.e.*, precess) about a vertical axis (*i.e.*, the steering column). The direction of this precession is such that the forward edge of the wheel moves toward the side of falling.

The bicycle then moves in a curved path, and the centrifugal force thus produced combines with the gyroscopic torque due to the precession to bring the bicycle up to the normal position again.

The main effect of "castoring" the front wheel is to cause the centrifugal force and the road friction to form a couple tending to restore the plane of the front wheel back into the longitudinal plane of the machine ready to counteract another tilt.

All the above described movements are, of course, interconnected, and can only be completely explained mathematically.

In an article in the *Automobile Engineer* for October, 1915, I went into the whole subject, obtaining several interesting results. For instance, the beneficial effect of "castoring" the front wheel was demonstrated, and an explanation was given of the process of steering a bicycle by body movement without touching the handle-bars.

Account was, of necessity, taken of the precessional motions of the front wheel, and the resulting effects due to centrifugal force and gyroscopic action, which Mr. Jones so lightly dismisses. GEORGE S. BOWER.

[We purpose to publish extracts from the article to which our correspondent refers when space permits.—ED.]

PETROL FOR THE MUNITIONEER.

Sir,—In expressing my opinion on the munition worker and his cries for petrol, I am voicing the opinion of many motor enthusiasts who are in France.

We who have spent three years out there, and to whom motor cycling is a forgotten pleasure, are disgusted with *some* of the letters appearing in your paper. Since the war, these people have had week-end joy-rides until the shortage of petrol has called for drastic restrictions. Immediately *their* motoring is stopped, they fill your paper with their narrow-minded laments.

My advice to the young and single munitioneer who states "two gallons a month for that fresh air which is essential for my health"—to that man I say, "Join up and come out here. There is plenty of air in Flanders, and any amount of exercise. The Army will teach you how to keep fit. One day out here will make you realise that *we are at war*; and once you have got that, you will see my opinion of your unpatriotic and selfish request has been very mildly stated."

B.E.F. J. CARROLL, LT.

Exponents of Indian motor cycles, R. G. Buck and S. Pasmore, who set up a sidecar record between New York and Chicago. Their time for the 992 miles was 43 hours 20 minutes, which beats the previous record by 54 minutes.

EXHAUST POPPET VALVE DESIGN.

Sir,—I have read with interest the letter by "Olivos" in your issue of January 10th on my valve idea, and am sorry he should not have had the best results. May I assure him that, if his engine is a M.A.G., there is no reason why he should not obtain them, provided the valves are *correctly* ground in, and that the spring adjustment and *alignment* are right.

He writes that his valves were perfectly ground in. That may be as far as the actual matter of grinding is concerned, but without a doubt he has not *correctly* carried out this procedure. It should be done as follows: After the seats have been well ground, clean all trace of emery off the top seat of the valve and its seat in the cylinder, and then place some emery or grinding compound on the *lower seat in the cylinder only*, and continue grinding until the valve will no longer touch the lower cylinder seat; this gives a clearance between the lower seat in the cylinder and the valve which is required, and this clearance will always be maintained.

The reason why the grinding compound should be put in the cylinder for the last grinding operation is that, if it is placed on the valve, some of the compound when inserting the valve (to continue the grinding) will be caught and held by the top seat in the cylinder, and consequently the top seats will also be ground, not allowing the clearance, abovementioned, to appear.

When the valves are ground in in the manner above explained there will be but poor compression when cold, but when the engine is hot it will be perfect, which is as it should be, and this is because the valve expansion closes up this clearance.

Now if the grinding is carried out so that there is no clearance formed, when the engine is hot the expansion lifts the top seat of the valve from its cylinder seat, and allows the explosion to exert its pressure under the full surface of the top seating of the valve, causing it to lift, as has happened to "Olivos's," but the reason that he experienced no popping or lifting at slow speeds was because the leakage past the top seat was too great, whilst at high speeds lifting will happen if the grinding is not correctly carried out, and also if the springs are not exactly in dead alignment or not exactly central over the valves, causing the latter to rub against the cylinders, and thereby losing the full elasticity of their springs.

"D.L.E." in your issue of December 6th last sets out the matter quite correctly, and he is right in his assumption that the valve rockers are exactly the same as were used with the ordinary type valves, but they are not proof against a solidly compressed spring at one end and a cam at the other, which can be the only cause of their fracturing, barring a seized valve stem with either type of valve; in fact, the valves are the only parts that have been changed.

As "D.L.E.'s" letter was written some weeks ago, I will reiterate his statement. He writes: "It is impossible for any lagging to occur." He is correct, and as the engines with suitable carburetter adjustments will turn over at 5,760 r.p.m. his statement is obvious. "Popping occurs only when the engine speed is too low for the load on the engine"—naturally, as there is far less compression at speed; "in other words, they act somewhat as safety valves, and retarding the spark stops the popping unless a change down is called for." He is right here also, but I wish to add that if the spring pressure is right and ignition timing likewise no popping will even then happen, the popping being also an indicator, advising one when to retard; but if the ignition is not retarded the valves act as safety valves, and the "pop" takes place instead of the "konk."

I have never found that popping would occur unless the valves were improperly ground, no matter how long or how hard the engine had been driven.

May I also assure "Olivos" that these valves do not require grinding, and are much better left alone? I do not allow mine to be touched, and they have not been ground for many years. I am using an engine made in 1912, and the seats on the valves and in the cylinders are as polished silver in appearance.

Now with regard to the levers, if the springs are so compressed that before the cam has reached its highest point the spring coils are in contact, naturally no lever will stand, and some part, of course, must fracture, provided that the engine can be turned over, and this has more than likely been experienced by "Olivos," as he mentions clearly that "when the valves were fully open it was impossible to move them at all." If the grinding be carried out so that the pressure can get under the top seat of the valves it is impossible to hold them down, but if the engine is run about 100 to 150 miles the valves will work into their correct clearance and remain so, though, of course, full power will not be obtained during that distance. OSBORNE DE LISSA.

GOODS MADE IN GERMANY!

Sir,—I have followed with keen interest the chain of correspondence on the above subject you have so kindly allowed to be published in your valuable and interesting paper. I may say I heartily appreciate the genuine spirit in which you have accepted the varied opinions, and it is a pure and fair intimation that at all times, and under any circumstances, the "Blue 'Un" is a perfect sporting journal, and indisputably repels the attack and pledges its belief in "playing the game."

Without fear of doubt, it has somewhat created a surprise to find that Mr. Chas. S. Ives (now a man of large kidney) has gained the favour of some more poor inoffensive supporters. Personally, I feel that their education on this vital subject has been seriously neglected. They are probably deemed to be patrons of the *Strafe Gazette*, in which it incessantly states that "Englishmen should not be allowed the breath of air." Still, Chas. S. Ives and his colleagues are firm believers in allowing the product of German sweated labour and prison-made goods to be dumped into English markets and cast the poor Britisher and his lot to the hospitality of the general community. But my motto is, "Let every Englishman be allowed to *live* in his own country." I am a fair judge in this direction, as I have personally seen in my own district untold sufferings amongst the people through foreign competition. Since the importation of German goods has justly come to a close the industry affected, I am pleased to say, is working as briskly as ever. Such instances prove that in your advertisement you have taken the "bull by the horns."

I am inclined to feel that I am trespassing too vigorously on your limited space, so, in conclusion, I can assure you that your esteemed paper has proved a boon and a blessing to the motoring fraternity, and I hope and trust you may not have been the financial sufferer and victim of sleepless nights as a result of Mr. Chas. S. Ives's childish decision.

E. O. ROBINSON.

Sir,—It was with considerable surprise that I read Mr. Tom E. Tanner's opinion on this subject. I should not have thought that one of our 1914 lads could have held such an opinion.

By refusing German goods, etc., I cannot conceive how we should be building up a German Prussianism at home. What would be the benefit of winning this war, if we were to allow Germany to use her skill and ability (both of which she undoubtedly has) to recapture the trade she had before the war?

No, sir, a German is a German, and he must be dealt with as such. When he begins to realise the cowardly and despicable part he has played in this war, then—and only then—is it time to commence to fraternise with him. No doubt we shall make friends, but not, I hope, until he has learnt his lesson.

I think Mr. Tom E. Tanner is perhaps *too* kind-hearted, and he might note that to do good we sometimes have to resort to painful methods. Germany is like a very wicked child who requires "licking into shape," and it cannot be done by half measures.

I heartily agree, sir, with the attitude you have taken, and am sure the supporters of Mr. Chas. S. Ives are vastly inferior to those of the Editor of the "Blue 'Un."

Durham. NORTHERNER.

Sir,—May I say a word in condemnation of the attitude taken up by Ives *et hujus generis illis?* How can your matured decision to decline to touch the money of murderers, thieves, and worse be called "Prussianism"? How can an honourable man take the money of scoundrels without some association with them? And there are two wise sayings—"Birds of a feather," etc., and "If we touch mud some of it will stick."

You may be assured that the greater number of your readers agree with you—since surely motor cyclists as a whole are honour-loving Britons, hence the enlistment of despatch riders. I have seen part of France—I have been through more than one Zeppelin raid—my great friend was stabbed in seventeen places; but not for this would I support you. We must forgive our enemies, but there is absolutely no reason why we should penalise our own good lads and allow the Hun the run of all his old trading facilities. The man who tries to sell me German-made stuff had better get a move on into the next parish one time.

Forgive such a long letter on the ground that, as an invalid and a lazy man, I should not have troubled to write unless interested. E.C.H.

Worcestershire.

FLYING FACTS AND THEORIES.

Sir,—One point seems to have been overlooked by Mr. Aston and his critics in considering the question of the effect of any departure from a direct course in producing a change in the pilot's own sensations, or in the power required to drive the machine, namely, the gyroscopic effect of the propeller, or, in the case of a rotating engine, of the engine itself. This effect is more marked in the latter case, of course.

Without going into a rigid proof, the following will suffice to give some idea of the nature of the gyroscopic forces brought into play by any change in direction.

Consider the rotation of the engine without any reference to other forces involved in flight.

If I = moment of inertia of all parts rotating about centre of shaft,
α = constant angular acceleration (radians per sec. per sec.),

Then torque, T, required to maintain constant acceleration α,

$$T = I\alpha \quad \dots \quad \dots \quad \dots \quad \dots \quad \dots \quad (1)$$

If a body starts from rest, acted on by a constant couple T lb.-ft., for t seconds, then the angular velocity (ω) at the end of t seconds will be

$$\omega = \alpha t$$

$$\text{Whence } \alpha = \frac{\omega}{t}$$

Substituting in (1) for α,

$$T = \frac{I\omega}{t} \quad \dots \quad \dots \quad \dots \quad \dots \quad \dots \quad (2)$$

If T = couple required in lb.-ft. to turn machine in any plane at right angles to plane of revolution,
ω_1 = angular velocity of the engine, etc., about an axis through the centre of rotation,
ω_2 = angular velocity in a plane at right angles to ω_2,
t = time required to make a complete turn of (ω_2),

Change in angular velocity in one complete turn of (ω_2)

$$= 2.\pi.\omega_1$$

Therefore, total torque required to turn engine, etc., in a plane at right angles to its own plane of rotation—

$$T = \frac{I.2.\pi.\omega_1}{t}$$

$$\text{but } t = \frac{2\pi}{\omega_2}$$

$$\therefore T = \frac{I \times 2.\pi.\omega_1}{2.\pi.} \times \omega_2$$

$$= I\omega_1.\ \omega_2.$$

This also accounts to a certain extent for the loss of speed in turning.

The fact that the torque, as given above, acts in a plane at right angles to that of intended flight may seriously upset the pilot's sense of direction, for in an aeroplane, which is absolutely unrestrained in space, this force will manifest itself at every turn of the machine. In turning sideways, for instance, there will be a tendency for the nose of the machine to rise or fall according to the direction of the turn. This, coupled with the ordinary banking effect, gives rise to the side-slipping and spinning so often experienced by pilots.

C. F. LLOYD.

DRIP FEED LUBRICATORS.

Sir,—I notice an article in *The Motor Cycle* of November 29th, which says that visible drip feed lubricators are proving a wash-out, and on this point I am afraid I cannot altogether agree with the article.

I have a 6 h.p. 1913 Enfield combination, and I can safely say that I have had practically no trouble with the vacuum drip feed which the Enfield Co. fits on its machines; in fact, the only trouble I have had (and that only twice) was the chocking up of the oil pipe with dirt.

To my mind, it is an ideal lubricator, as the faster the engine revs the faster the oil flows; and it has this great advantage, that it is safe from small youths playing with it and over-oiling the engine, and one can set the regulator and leave it in that position, and it will do its work efficiently until the oil in the tank is exhausted. In addition, the Enfield Co. has a hand pump with a two-way tap, which one can use in an emergency, and which also feeds the gears.

A SATISFIED ENFIELD RIDER.

SPRING FRAME DESIGN.

Sir,—I should like to suggest one or two little points for criticism in the Warner spring frame design illustrated on page 70 of your issue of January 17th.

This design appears to be almost the same as the old P. and M. front fork, which was unsatisfactory owing to the wear on the pins at the various joints.

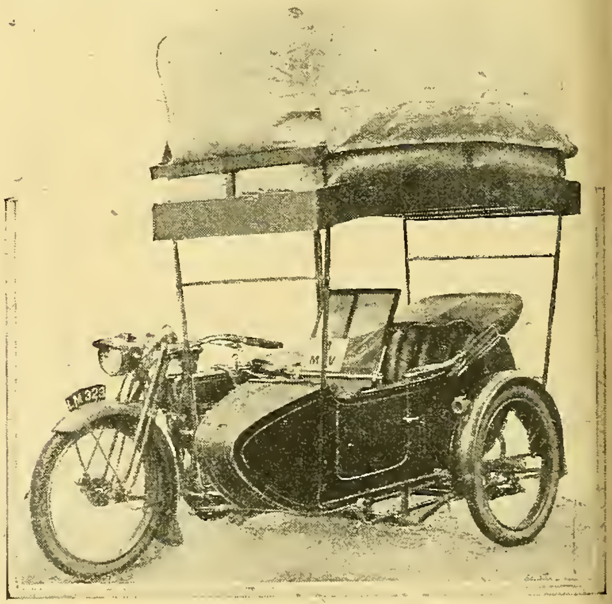
I am sure that Mr. Warner's system would give trouble in practice, owing to the short shackle pins being cut into by the plates which carry the hub; the holes in the plates would also rapidly wear oval.

The spring in its present position necessitates high saddle position, high carrier, and long wheelbase.

It would be better to attach the rear stand to the rigid part of the frame, since in its present position the whole weight of the machine is on the spring with the stand in operation, which will render adjustments to the springing system somewhat difficult.

Spring frames are undoubtedly attractive, but it seems a far cry to anything in that line ever approaching the grace and symmetrical outline of a certain much-abused front fork (which shall be nameless). Perhaps the P.V. as it was sold in 1913 was as satisfactory as a spring frame could be in general lay-out, but possibly it was not adaptable for countershaft or chain transmission, as I remember it was sold with an engine-shaft gear; nevertheless the design had the merit of simplicity.

M.T., A.S.C. WHARFEDALE.



SIDECARING WITH COAL GAS.

A Harley-Davidson outfit fitted up to run on coal gas by J. A. Masters, publicity manager of the Harley-Davidson Motor Co., Ltd., London. It has been given a very fair testing and found satisfactory, although the power on hills does not compare favourably with that obtained on petrol. The gas is taken by a ⅜in. pipe through the extra air port of the Schebler carburetter, and the supply is controlled by a tap just before entering the carburetter. The automatic air valve is not interfered with, and operates in the usual manner. Except at high speed no ill effects have been felt in consequence of the extra wind resistance.

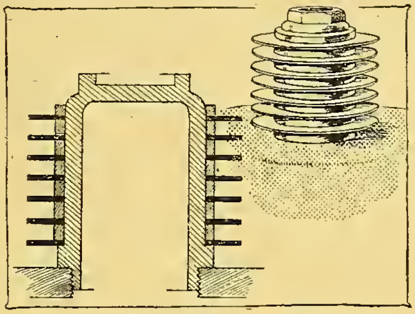
A Compression Reducing Valve Cap.

An Arrangement whereby Compression may be Reduced and Extra Cooling Provided.

MANY motor cyclists have tried experiments with the object of reducing the compression ratio of heir engines, and to meet such a need t. C. S. Burney, of Durrants, Northhurch, Berkhamsted, has recently atented a special valve cap. This cap, as nay be seen from the illustration, conists of a cylinder that projects above he normal valve cap opening, and is lso provided with radiating fins after he fashion of those on an ordinary airooled engine.

Details of Construction.

The working of the device should be airly obvious, but we may point out hat the patent cap is intended to relace the standard fitting, and, of course, s made in the correct sizes for various ngines, so that this may be done quite asily—by simply removing the old cap and inserting the new one. The radiating fins, made of some such metal as copper or aluminium, are detachable, and are held apart by distance pieces that are also detachable, so that the number of fins on the cap at any particular moment may be easily varied to suit the needs of the engine to which it is fitted. Obviously all engines do not require the same amount of extra cooling, and provision is made for this in the detachable construction of the fins and the use of the detachable distance pieces.



A device for lowering compression and increasing cooling area of an engine.

Adaptability.

There is no reason why valve caps of different depths should not be made for engines of the same type, so that the extent to which the compression is lowered may also be easily altered by the fitting of a different cap. The same fins, of course, would fit whichever cap happened to be in use.

Judging from the number of queries we are continually receiving *re* compression reducing devices we should be inclined to prophesy a ready market for this valve cap.

◆

Some Criticisms of Front Brake Design.

Weak Points of the Rim Brake. A Good Alternative.

SURELY it is time manufacturers woke up to the fact that motor cycles need something more satisfactory than the ordinary stirrup type of glorified push-cycle front brake.

On four out of five machines these brakes are entirely out of action; in fact, in some cases motor cyclists absolutely refuse to have a front brake of this type on their machines, and among the first things they attend to is the front brake, and their attention takes the form of entire removal and consignment to the nearest rubbish heap. In fact, they are prepared to risk the law rather than keep such a brake on their machines.

Some Disadvantages.

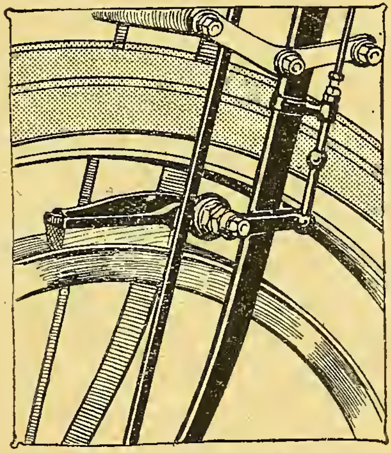
The reasons why the stirrup type of front brake is unsatisfactory are many. It fits close to the tyre, and is very easily clogged when muddy roads are traversed in a day's run. If the rim be the least bit dented—and any all-weather motor cyclist knows how a rim becomes dented when travelling fast on a rough road—and the tyre gives, then the brake power is exerted in jerks, and that is the one way in which brakes must not be applied, because on wet roads skidding is caused, and on dry roads unnecessary jars are communicated through the frame. They rub enamel off the rim, so rims on which these brakes act are usually plated, and thus the weather-resisting properties of the machine are seriously impaired.

A few makers of motor cycles—notably the B.S.A., the Enfield, the Allon, and the Lea-Francis—get over the difficulty by mounting a brake rim with a single large shoe, similar to a rear brake, acting on it on the front wheel, or, in the case of the lightweight Allon, a drum with a coil round it. The Indian and Excelsior and others, on the other hand, fit two brakes—one hand and the other foot-operated—on the back wheel, and thus evade the difficulty entirely.

The brake fitted to the heavyweight Allon, to my mind, rather falls short of the mark. As it is applied on the hub side of the brake rim, it has to be moved before the wheel can be taken out, unlike the B.S.A., Lea-Francis, Enfield, and others. I hope the Alldays and Onions company will pardon this criticism of their otherwise excellent machine.

The Lea-Francis.

In one of the last trials before the war, marks were given at the finish for machines having both brakes still working properly, and the Lea-Francis machines gained these marks, while many others had their front brakes totally out of action. This certainly speaks volumes for the type of brake with which the Lea-Francis was fitted, and this machine was among the first to adopt this type of brake as a standard fitting.



A type of front brake advocated by the writer.

Surely, when these brakes are less liable to go wrong, are more powerful, and do not interfere with the removal of the wheel, it is obvious that they are superior to the old stirrup type, which is merely an enlarged edition of a push-cycle brake.

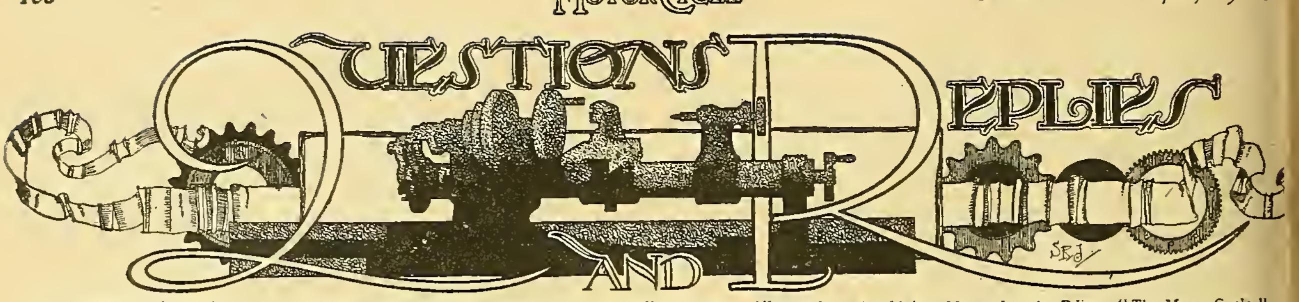
In my opinion the front brake is the one feature on almost every British machine deserving of condemnation. ARGON.

GAS PERMITS.

New Order in Force February 10th.

THE Board of Trade has issued the following announcement:

Under the provisions of Clause 11 of the Motor Spirit (Consolidation) and Gas Restriction Order, 1918, motor vehicles fitted with gas apparatus may not be driven after February 9th without a gas permit issued by the Petrol Controller. Forms of application for gas permits will be furnished on request by the Petrol Control Department, 19, Berkeley Street, London, W.1. If the motor vehicle were fitted with gas apparatus before January 3rd, 1918, or has since that date been fitted with apparatus ordered before December 21st, 1917, a gas permit will be issued on application, subject to certain conditions. If, however, a motor vehicle is not at present so fitted, or if the order for the gas apparatus has been given since the intention to restrict the use of gas was announced, the application will be considered on its merits, and a gas permit will be issued only in those cases where a motor spirit licence would otherwise be granted.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Carburetter Flooding.

? Please let me know what would be likely to make my engine miss three or four times in succession when the machine gets a heavy bump on the road. The carburetter and petrol pipes are clean and the plug wire is secure at both ends.—M.K.

The trouble is probably due to the fact that the bumping causes the carburetter needle valve to bounce off its seating, allowing an excess of petrol to enter, which upsets the mixture, making it temporarily too rich.

Advice on Tyres.

? I have a 3½ h.p. sidecar combination (registered weight 220 lb.); my own weight with coat is about nine stone. I generally take a passenger weighing about twelve stone, hand luggage, and a tin of petrol. (1.) With such a weight, and taking into account the present state of the roads, how long do you consider that *(a)* sidecar, *(b)* front wheel, and *(c)* back wheel tyres should last? The tyre used was heavy, 26×2½in., to fit 2¼in. rims. (2.) How many miles should a heavy tyre run on the back wheel before the pattern is worn off? Mine seemed to wear smooth almost at once. (3.) Do you consider that *(a)* vulcanising or *(b)* retreading pays? If so, at what stage should it be done? (4.) What can I do to make my tyres last longer, or what can I avoid doing? I ran a heavy cover for 1,185 miles (493 on sidecar, 692 on back wheel), and at that distance it had worn in six places, each 2in. long, through to the canvas. An extra heavy tyre on the back wheel lasted only 869 miles. I use my brake a fair amount in traffic and on hills, but always very gently and lightly, and so far as I know have never dragged my wheel. (5.) What can be done to avoid a burst in the inner tube by nipping? I have had both sidecar and back wheel tubes burst with loud bangs, and when I looked I found the outer cover had come off from the rim on one side, and there was a huge gash in the inner tube. Both tyres had been put on at garages, and the sidecar tyre had run about two hundred miles and the back tyre about five hundred miles before it occurred. I should have thought that if they had been nipped when put on they would have burst at once.—(Miss) E.M.G.

(1.) It depends entirely upon your manner of driving and cornering, the speed at which the outfit is driven, and the alignment of the sidecar. You should get about 2,000 miles out of the back tyre, and another 2,000 with it on the front or sidecar wheel; about 4,000 out of the front, if retained in that position; and rather more on the sidecar wheel. (2.) If a good tyre, about 1,500 miles. (3.) Vulcanising is quite satisfactory if properly done, but retreading is only to be recommended for a tyre used on the sidecar or front wheel. It should be done as soon as the tread gets thin. (4.) The tyre should be of ample size, and should wear quite well. We cannot understand why yours should be so unsatisfactory, unless it is that you drive a machine possessing a very harsh drive. Are you sure that the alignment of the sidecar is correct? (5.) By fitting the tyre carefully. Bursts are nearly always caused by careless fitting. The tube should have a little air in it when being inserted, and it is best, if possible, to avoid the use of tyre levers when replacing the tube. Often when a tyre is nipped it will travel some distance before bursting.

Speedometer Drive for Different Sizes of Wheels.

? Can I fit a speedometer constructed for a 24in. wheel to a machine with a 26in. wheel, and still get reliable readings?—W.H.L.

Your object may be achieved by using a driving pinion for a 26in. wheel. The makers of the speedometer will supply you with whichever size pinion you require.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY.

During 1918 the restriction on the import of paper and paper making material is very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week.

Local Taxation Licence Exemption.

? I have used my motor cycl twice this year before January 21st, on both occasions for Red Cross work. Would you pleas let me know if I need pay the £1 tax, as I understand that one can claim exemption for Red Cross work —H.M.S.

There is no exemption. Under the circumstances, you will have to pay the local taxation licence.

Difficulty in Changing Gear.

? My machine is a 7-9 h.p. two speed, and my difficulty is that I cannot change from high gear to low or low to high whilst the engine is running, and if I start the engine at a standstill the clutch will not respond when let into engagement. The only alternative I have is to let in the clutch first, and start with a push, and even then the clutch will often slip out when climbing a stiff hill, or if the engine becomes at all hot. Also, why is my machine so hard to start? Once the engine is warm it will start with a turn of the kick starter, but not before. The points are set right, and the timing is correct.—F.K.

It is possible that your trouble is due to the gear box being loose on the hanger bracket, with the result that the front chain has been tightened to such an extent by the rear chain dragging the box to the rear that the sprocket has been damaged. As you are probably aware, the clutch sprocket is fitted with a bearing ring on the inside and floats on rollers. If the bearing ring is damaged or pressed into the clutch sprocket, the said sprocket ceases to float on the rollers and bears on the edges of the plates, and the clutch is then very difficult to disengage. Also, it seems as if the edges of the dogs are rounded, and when you refer to the clutch jumping out on steep hills it is probably the dogs in the gear box which come out of mesh. We should advise you to take the clutch down and thoroughly examine the parts mentioned, and also adjust the gear operating rods, so that the dogs are thrown fully into engagement with a certain amount of tension on the rods. If after making the necessary adjustment the dogs still jump out, it will be necessary to have them either replaced or reground. As regards the difficulty in starting, we should recommend you to use a fairly thin lubricating oil. Are you sure that there are no air leaks at the induction pipe or carburetter unions, or at the inlet domes?

Pre-ignition.

?

My motor cycle goes very well for some time and then suddenly stops, but after a little time I can start it again. It also slows up going round corners and up ills.—S.G.

e should say that the trouble is possibly de to the use of an unsuitable plug. haps you are using one the points of ich project too far into the cylinder al cause pre-ignition, and this would aount for the symptoms described in ur letter.

Release Valve Requires Adjustment.

?

I have recently purchased a second-hand 1917 two-stroke, and noticed that the small tube leading from the release valve to the exhaust chamber was disconected, had slipped down into the hamber, and the orifice had been plugged with a piece of hard wood. After connecting it up again, with the plug removed, I notice that there is not the same power on hills, the low gear being necessary where previously one ascended easily on top gear. Can you kindly tell me whether the back pressure from the silencer, ascending the small tube, might cause the release valve to open slightly, and so lessen the compression; whether, if this be so, the fitting of a stronger spring to the release valve would overcome the defect? An unpleasant hissing noise is caused when the release valve is opened with the tube disconnected. Perhaps others have noticed this phenomenon, and can suggest a remedy. —ENFIELD.

e trouble is entirely due to the release lve requiring to be adjusted. It should screwed down a little so that it does t open too far. It is also most imrtant that the exhaust system of a twooke engine should be entirely free from ck pressure. It is, however, practically possible that this back pressure should strong enough to open the release lve, especially as this would mean ring open the release valve against mpression in the cylinder.

Automatic Inlet Valve Queries.

?

My motor cycle engine is a 9 h.p. a.o.i.v. 1909 J.A.P. It is in very good condition, runs well on the stand and when running on the flat, but I cannot get it to go up hill. Although I have thoroughly ground the valves in; there seems to be a good deal of blow-back in the carburetter. (1.) Would you advise me to have new inlet valves? (2.) Which is the correct way to time an a.o.i.v. engine?—S.A.S.

.) We should not like to say you eed new inlet valves, but these could e examined, and you should see that e lift is not too great—say $\frac{3}{32}$in.—and at the springs are fairly strong. (2.) ou have only to time the ignition and xhaust valve, which should be done as llows: *Magneto:* Place the piston xactly on top of the compression stroke, nd connect up the magneto with the oints just about to break and the ignion lever two-thirds retarded. This will ean that the explosion, when the ignition is fully retarded, will take place when the piston has travelled about 1.5 mm. down the firing stroke. *Exhaust Valve:* Set the exhaust valve to close just after the completion of the exhaust stroke. It will then commence to open when the piston is about one-seventh of the length of the stroke from the bottom of the firing stroke.

Motor Cycling Literature.

?

Can you recommend a good book on motor cycles and motoring matters in general?—F.W.J.

The best book for your purpose is "Motor Cycles and How to Manage Them," price 1s. 6d. (post free 1s. 10d.), while, when you have started riding, another excellent book is "Hints and Tips for Motor Cyclists," price 1s. 6d. (post free 1s. 8d.), both published from the offices of *The Motor Cycle,* 20 Tudor Street, London, E.C.4.

Dealing with Unknown Persons.

?

I am about to buy an Enfield combination from a London dealer, who wants my cheque before sending machine on approval. As I do not know anything about him, will you kindly advise what action to take before sending the cheque?—T.J.

In dealing with unknown persons the best course for you to adopt is to transact your business through *The Motor Cycle* deposit system, particulars of which are given every week in *The Motor Cycle* at the head of the first column of advertisements of second-hand machines.

Accumulator Charging.

?

I have an accumulator marked "Charging rate 7 amps," and am told this is 6 volts. I also have a mechanically - driven dynamo giving out 12 volts 12 amps. Will you kindly tell me the best procedure to charge the former by the latter?—W.J.C.C.

The voltage of your dynamo may be ignored, but you must not charge the accumulator at more than 7 amps. To do this, the accumulator should be charged through a number of 12 volt bulbs, the sum of whose amperage is 7 amps.—that is to say, seven 1 amp. bulbs (*i.e.*, 12 c.p.), or three 2 amp. (*i.e.*, 24 c.p.) and one 1 amp.

RECOMMENDED ROUTES.

GREENOCK TO BRADFORD-ON-AVON.—A.W.W.

Greenock, Glasgow, Hamilton, Lesmahagow, Abington, Beattock, Lockerbie, Ecclefechan, Carlisle, Penrith, Shap. Kendal, Lancaster, Garstang, Preston, Wigan, Warrington, Tarporley, Whitchurch, Hodnet, Wellington, Bridgnorth, Kidderminster, Worcester, Tewkesbury, Gloucester, Stroud, Nailsworth, Swainswick, Bathford, Bradford-on-Avon.

BEDFORD TO DOVER, *viâ* LONDON.—G.R.R.

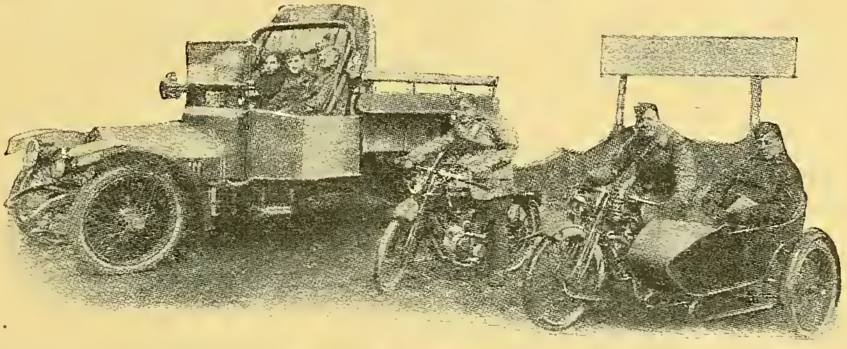
Bedford, Luton, St. Albans, Barnet, Finchley, Baker Street, Marylebone Road, Portland Place, Regent Street, Pall Mall, Cockspur Street, Whitehall, Westminster Bridge, Westminster Bridge Road, Kennington Road, Camberwell New Road, Peckham Road, Queen's Road, New Cross, Lewisham, Sidcup, Wrotham. Maidstone, Charing, Ashford, Hythe, Sandgate, Folkestone, Dover. Approximately 120 miles.

The route *viâ* Crayford,, Gravesend, Chatham, and Canterbury is perhaps flatter, but there is an enormous amount of traffic out of London and as far as Chatham.

READER'S REPLY.

Release Valve Adjustment.

I noticed recently in your valuable journal that a rider complained about his machine (a two-stroke) refusing to take air. Now I have a Villiers two-stroke machine, which had the same symptoms, and this little tip may be of some use to two-stroke riders. I could not get my machine to take air (Senspray carburetter). It would always splutter and "pop back." Recently I started to investigate, with the result that my machine now runs perfectly again. This would only apply to Villiers two-strokes with the release valve on the top of the cylinder. After overhauling the magneto, carburetter, and anything else I could find, I tried the release valve, the spring of which I found to be weak, so I fitted another new one, and also ground the valve in for about five minutes, and replaced it. I have since ridden some hundred miles, and it has not missed once, and also it will take hills much more easily than before. I have ridden several makes of machines, including big twins, but find the two-stroke as good as any for reliability.—S. H. ARTHUR (Newcastle, N.S.W.)



A P. and M. motor cycle and sidecar outfit sent over to Canada for the use of the Royal Flying Corps in the training camps of that country. P. and M.'s, as is well known, are used by the R.F.C. in this country.

("Motor Cycle and Bicycle Illustrated," New York.)

SPARKLETS

The Warner Spring Frame.

Mr. J. Warner, of 111, Munition Cottages, Holbrook Lane, Coventry, informs us that he is willing to correspond with anyone, especially manufacturers, interested in his invention, described in our issue of January 17th, primarily with the idea of launching it on the market.

Census of Tyres.

Which is the most popular tyre amongst Australian motorists? An accurate answer to this oft-discussed question was provided by the great collection of cars paddocked on Melbourne Cup Day, a census of the tyres fitted revealing the fact that the Dunlop easily carried off the honour. Altogether 3,324 tyres were checked, and of this total 1,538 were Dunlops, the balance being spread over thirty other different makes.

An Attractive Sidecar List.

We have received an interesting advance leaflet of Phœnix sidecars from the makers, the Phœnix Sidecar Works, Holloway, London, N. This leaflet is about 20in. × 10in., and contains full illustrations and specifications, together with prices, of the various sidecar productions emanating from the Phœnix Sidecar Works. Many of the models are of extremely pleasing design, and all such accessories as various types of hoods and screens are fully illustrated. There are two of these leaflets, one containing illustrations of complete sidecars, the other of sidecar bodies and fittings alone. Readers should state which they require when applying. It is also interesting to know that the makers hold a very large stock of sidecars, and are in a position to supply them.

The Welding of Metals.

There is an interesting article in the current issue of *System*, the business magazine, entitled "Recreating War-worn Machinery," by Mr. C. W. Brett, managing director and general manager of Messrs. Barimar, Ltd. It is not generally known among motor cyclists that Mr. Brett first began business with Werner Motors, when they had a depot in the very early days of the movement just off Regent Street.

The firm of Barimar has had a very fine record during the war, and has brought back into commission more than 20,000 fractured machines now engaged in work of national importance.

The article gives a full account of the interesting processes of electrical and oxy-acetylene welding, and also refers to the Thermit process, which was invented by a London metallurgist who disposed of his rights to a German. The process has now been taken up by Messrs. Barimar with great success.

The Palmer Tyre Calendars.

The Palmer Tyre, Ltd., 119-123, Shaftesbury Avenue, London, W.C.2, inform us that owing to the paper restrictions they are unable to reprint the Palmer calendar, the stock of which has entirely run out.

Repairs to Dixie and Splitdorf Magnetos.

Repairs or spare parts of Dixie and Splitdorf magnetos can be quickly furnished by the direct factory representatives, the American Supplies Co., Ltd., of 162, Great Portland Street, W.1.

English Motor Cycles for U.S. Army.

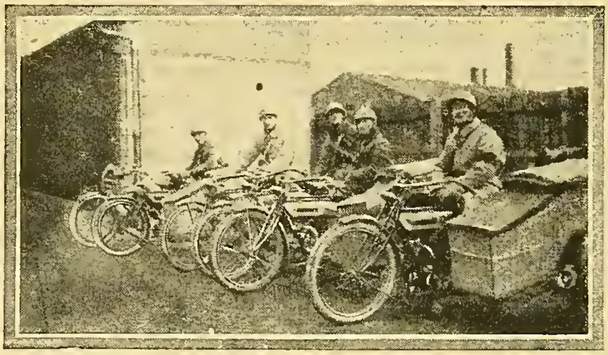
A considerable number of New Imperial 8 h.p. motor cycles have been ordered for the U.S. Army for use in France, and numbers have been already despatched. Also an order has been placed for New Imperial 8 h.p. machines by the Royal Naval Air Service.

Another Advance in Prices.

H. Miller and Co., Ltd., Miller Street, Birmingham, the manufacturers of the Miller Lightgivers, regret that, owing to the continual rise in cost of raw materials and labour, an entire revision of their selling prices has become necessary.

Parkside Reorganisation.

We are informed by the Parkside Motor Engineering Co., Ltd., Parkside Works, 28½, Sheen Lane, East Sheen, London, S.W.14, that the company will in future be known as the Nowell and Cox Engineering Co., Ltd. The new company, with a capital of £10,000, has taken over the whole of the works from the former company. Mr. Douglas Cox, who has had fifteen years' motor engineering experience, will assume the position of managing director, while Mr. W. J. Nowell will remain general manager.



Group of motor cyclists in the French Army with their Triumphs. The wicker sidecar is a feature distinctive to the French Army. It is used chiefly in the Commissariat Department.

Gas Filling.

We are informed by Messrs. Dews and Dyson, Town Hall Buildings, Brighouse, Yorkshire, that at their new premises at Police Street, in that town, they have installed a 100 light meter, and they are therefore now able to fill gasbags of any capacity in as short a time as possible. A meter of this size should effect a saving in time.

Buying a Tank.

The employees and managers of tl Metropolitan Carriage, Wagon, an Finance Co., Birmingham, have decide to purchase a Tank in the name of tl firm, and present it to the Army.

J. B. Brooks and Co., Ltd.

Although the company's resources a very considerable, and its facilities make are second to none in the trad it wishes to make it quite clear th orders given to travellers for forwa deliveries can only be accepted on tl terms that they are invoiced at the pri at which they can be manufactured the date of despatch.

With the coming of the new Ma and Woman-power Scheme it is ve difficult to know what the future has store, but the reputation of Messr Brooks and Co., Ltd., added to a car ful regard for after-the-war busines will be a guarantee that customers w continue to be as well served as possible.

Middlesex Motor Volunteers.

The motor cyclists attached to tl Heavy Transport Section of the Coun of Middlesex Motor Volunteers (Easte Group) have been recruited entirely fro the ranks of Harley-Davidson riders.

A series of lectures and demonstr tions on the Harley-Davidson mot cycle has been arranged for the bene of the motor cycle members in additi to the drills and parades.

There are at present vacancies f three motor cyclists, and any Harle Davidson rider resident in the Lond area who is interested should commu cate with Sec.-Lt. J. A. Masters, 7 Newman Street, London, W.1.

Birmingham Tank Bank.

One of the first and most encouragi contributions to the Tank Bank Birmingham when it opened on Decemb 31st was one from the employe of the B.S.A. Co. for £77,50 which had been subscribed f the purchase of 100,000 W Savings Certificates, making total of £205,000 invested War Loans by the B.S.A. wor people. The B.S.A. directo have set a fine example enabling their employees invest in War Loans, by pu chasing a large amount a allowing the employees to p off the amounts out of wage If all employers would car out a similar scheme, it wou mean that even in the four year of the war record sum would be subscribed. Th B.S.A. Co. have subscrib £300,000 through the Birmin ham Tank Bank, and the example has been widely copie

A New Depot.

The New Rover Cycle Co., Ltd., Co entry, inform us that they have mov their London depot from 19, Holbo Viaduct, London, E.C.1, to No. 18, account of the expiration of the leas The new premises, we are given understand, are more commodious a convenient.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns—First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☛ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller. but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

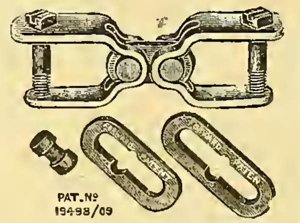
A Good Belt and a Good Fastener.

If a poor belt is fastened by a good fastener the latter may effect its purpose perfectly, but it can never overcome the belt's deficiencies.

On the other hand, if a good belt is fastened with a poor fastener all the "goodness" of the former counts for nought.



THE FORWARD, 1/6.

THE FORWARD will always do its work effectively; it is "the fastener that never fails."

It is worthy of the finest belt produced—yours, for instance—and its merits ensure long life and perfect service.

There are several models—we illustrate the Forward—but don't forget the KING HOOK, "King of all hook fasteners." **1/-** detachable, **1/3** adjustable.

Motor Cyclists and the United Council.

THE United Council of Motor Users, Producers, and Distributers has been formed, and it appears to be for our readers to decide whether this new body shall receive the support of motor cyclists. Such support can be given through the Auto Cycle Union and through the Automobile Association. As regards the latter, assuming that the A.A. as a whole decides to participate, the motor cycling membership should certainly not be left without direct representation. At present, if rumours can be relied upon, the A.A. is holding aloof, which we think is a great pity. As regards the A.C.U., we have as yet no official information as to the attitude adopted.

The position of the A.C.U. is, in a sense, a somewhat difficult one. This is not a time at which a really representative general meeting can be called, or a plebiscite of the members taken with any certainty of arriving at the right result. This being so, one can well understand that the Committee may be reluctant to take any action which may appear to commit the members irrevocably to some policy which might not represent their real views.

At present the constitution of the Council is somewhat indefinite, but, nevertheless, certain main principles have been clearly adopted. One of these is that the user shall predominate in the Council, over the manufacturer or the distributer—in fact, over the two together. With this principle the motor cyclist must obviously be in agreement. He does not intend to be "run" by the Trade, but he presumably has no objection to the Trade lending its influence to support his own policy. Similarly, he can have no objection to collaborating on occasion with the motor car owner and the industrial vehicle user, provided that his interests are not subordinated to theirs. By such collaboration he may be able to avoid unseemly squabbles in public over matters of detail far better settled by compromise in private. He cannot, however, take any risk of being tongue-tied by any agreement to support a majority resolution of a body in which he has only a minority vote. To do this would be to render the A.C.U. impotent when its policy was out of agreement with that of, let us say, the Royal Automobile Club. As regards this point, one of the first stated principles of the new Council is that it will not take public action except as the consequence of a unanimous resolution. When unanimity proves impossible, the bodies forming the majority could, and probably would, forthwith form a joint committee to advocate their policy. The minority could take similar action, and would at least have the advantage of knowing exactly how matters stood, and what lay behind the exponents of the opposite point of view. If the A.C.U. supports the Council, then it has the power of preventing the Council, as such, from doing anything of which it disapproves.

What the whole thing comes to is, therefore, this. While the Committee cannot consult the membership as a whole, ought it to take steps to restrain the actions of the United Council or not? It seems to us that the governing body of the Union will not be doing its full duty to the membership if it neglects to take such steps. Were it to fail to do so, then, if the Council were to take public action evidently detrimental to motor cyclists, would not these latter have a legitimate grievance against the Union for having failed to protect them?

We should welcome the opinions of individuals on this question. Meanwhile, we believe that we are expressing the views of the majority of motor cyclists in advising that the A.C.U. should appoint delegates to the United Council, if only for the purpose of holding a watching brief, and not with a view to initiating action on lines that motor cyclists could conceivably regard as being open to controversy.

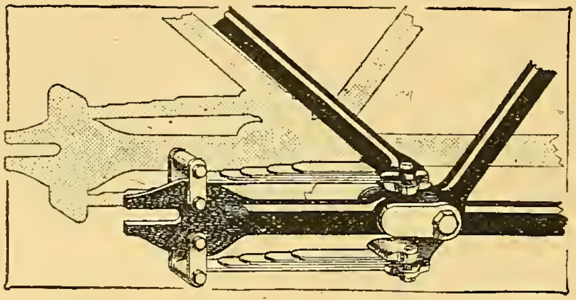
Another Rear-springing Arrangement.

A New Rear-springing System emanating from the Bat Works.

AMONG the many recent and promising arrangements of a rear-springing device is a patent by Mr. T. H. Tessier, of Bat fame. The Bat machine, of course, has been justly famous for years for the excellence of its springing systems, and anything new emanating from such a firm carries with it the hall-marks of quality and experience.

In its form as illustrated the device necessitates the use of four separate leaf springs. Briefly, the idea may be described as follows: The normal rear fork ends are replaced by special lugs carrying fork arms that are sprung, and at the ends of which is fitted the rear spindle of the wheel in the ordinary way. The two arms projecting from the lugs are able to swing round a pivot and are controlled in the extent of their movement by the action of the leaf springs.



A recent springing patent by T. H. Tessier, of the Bat Motors.

The Springs.

The actual number of the controlling springs may be varied if necessary either in so far as the number of their members—to determine their amount of elasticity—is concerned, or, instead of there being tw springs to each strut, there may be only one. Mor over, leaf springs may be replaced by springs c some other type, *e.g.*, the coil or helical type, thought desirable.

While the principles c construction involved in tl device seem to us to be qui sound, we must confess th the general appearance seen somewhat over-elaborate, an we should imagine that son of the parts would be liab to premature wear. One c the main advantages claime is the provision of a re springing without the loss c lateral rigidity, but we shoul be inclined to the criticis that, while lateral rigidit may have been retained, it has been so at the expens of flexibility in the springing. Perhaps the provisio of weaker springs or of a fewer number of sprin would remedy this, but we have no doubt that th designer has gone into the matter very thoroughl and that he has satisfied himself as to the capabiliti of his design before arriving at any such definite sta as that which the arrangement has now attained.

* * *

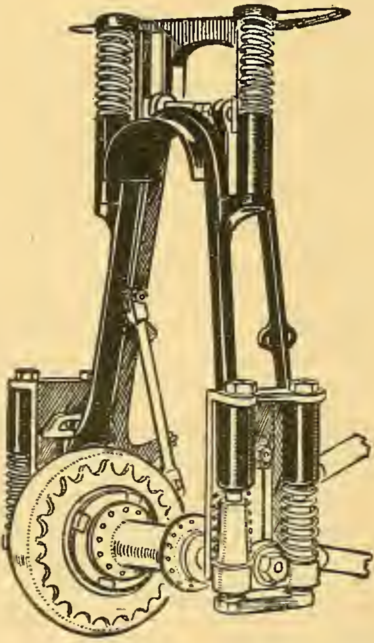
A Springing Device and Detachable Wheel.

An Invention that includes Simplicity in its many Good Features.

IT was in *The Motor Cycle* of March 23rd, 1916, page 274, that we described an extremely ingenious detachable wheel which was the invention of Mr. David Levy, 19, Drewstead Road, Streatham Hill, London, S.W. Mr. Levy has incorporated this invention in an excellent design for a rear-springing device which he has lately introduced. As the two are so closely connected, we reproduce the illustration of the detachable wheel and transmission shock absorber so as to remind our readers of its working.

Removal of the Wheel.

The simplicity with which the wheel is removed by undoing one nut and withdrawing the spindle, distance piece, and washer is quite remarkable. as is also the ingenious transmission shock absorber, consisting of a coil spring, one end of which is attached to the periphery of the brake drum and the other to the driving portion. In the event of the spring giving way or becon ing detached, dogs are provide which will allow the drive to b solid.



A detachable wheel and rear-springing device by Mr. D. Levy, Streatham Hill.

Springing.

As regards the rear sprin ing arrangement, the whole of th portion, consisting of the inner pa of forks which hold the wheel, i suspended on six coil springs, whic are partially, but, if desirable, ma be made entirely, enclosed. A sliding parts are provided with ampl bearing surfaces, and the slides i the top portion above the rear mu guard stay are provided wit means of adjustment so that th degree of friction in working ca be varied.

The whole idea is beautifull carried out, and should be we worth the attention of a manufa turer who has not yet decided upo any particular form of springin and most manufacturers should ha decided by now that some form c rear springing is advisable.

Occasional Comment

BY IXION

A Minor Difficulty.

T is quite probable that noisy valve gear will distinguish some of the earlier novelties in the way of hot-stuff engines. It is, of course, absurd fancy that the expansion of the cylinder under heat as been eliminated. The hoodoo which has been cotched is uneven expansion, better known as disortion. In the process even expansion has somemes risen to a larger percentage. Indeed, it is coneivable that if the tappets of a post-war hot-stuff otor cycle engine were adjusted to the correct learance when the engine was cold the clearance ould become excessive when the cylinder warmed up. hus it is on the cards that some of the early peace ngines will be designed to run with a tappet clearance hich will not make for silence.

The Composite Cylinder.

"ENGRO'S" article in the issue of February 7th was tantamount to a claim for the embodiment of aero engine practice in the motor ycle practice of the future. He practically suggests eparate combustion heads, and separate valve pockets, s alternatives to the single-casting method of construcion: and he only departed from aero engine practice n retaining the side valves, probably with the idea of educing overall height and providing plenty of tankge space without rendering the machine too high. s some readers have hinted that aero engine practice nvolves increased cost, it is interesting to notice that, o far as labour goes, the types of engine described y "Engro" would probably be cheaper than the ingle casting of pre-war days. Each item is extremely anageable, and the various machining jobs can mostly e done at a single mounting: by contrast, the old ype of 3½ h.p. cylinder is at once a complex casting nd a complex machining job, for both of which easons the percentage of duds was rather large, and arts often had to be scrapped on which a good many ours of labour had already been expended.

Two Flies in the Ointment.

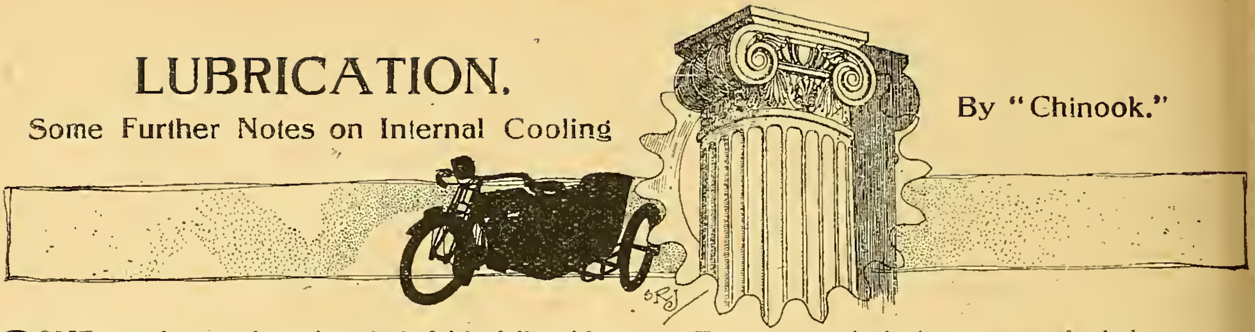
THE first potential hitch in such designs, as applied to motor cycle construction, is connected with the cost of metals. I presume that "Engro's" istons and bolted-on valve pockets are to be made f some aluminium alloy; what will aluminium cost fter the war, as compared with iron, or even with eel? The second turns upon even expansion under eat. His cylinder barrel is obviously a homogeneous, ell-balanced piece of work: as it gets hot, it will xpand evenly without distortion, especially if the bs are properly designed, and the exhaust valve is ocated at the rear (the hotter side), with the inlet at he front (the cooler side). Still, there will be a marked heat expansion in the combustion head, whether it is detachable or not. If this expansion is even, and no distortion occurs (which is a large order), what will happen to the bolted-on valve pockets? Can it be guaranteed that they will expand in the same ratio as the head, to which they are bolted? If they do not, we shall get the exhaust blowing at one pocket joint, whilst air leaks at the other will spoil our carburation. If the valves are seated in the pockets, this will affect the compression as well: but if the valve seatings are machined in the combustion head itself, the compression will probably be trustworthy.

In the Air v. on the Road.

IT is probable that many designers have solved all these problems in such practical aspects as flight presents. It remains to be proved that the extreme ranges of engine temperature encountered in the air and on the road are sufficiently parallel for one solution to fit both sets of circumstances. In flight an engine has to cope with a blazing summer sun at ground level and with positively Arctic temperatures up towards its ceiling. But the variation between these extremes is presumably narrower than the scale of heat and cold over which a motor cycle engine may range during quite a humdrum trip. After all, an aero engine is almost a fixed speed engine while it is at work: if its normal r.p.m. are, say, 1,250, its maximum revs. will possibly not exceed 1,500; and, again, it is guaranteed fairly stable atmospheric conditions. If its cooling is assisted by wind scoops, the speed of the wind into those scoops does not vary over a really wide margin, and the minimum speed is pretty high. If it is a rotary, and relies on its own breath, so to speak, the current which it creates is moderately stable. On the other hand, the motor bicycle engine is required to behave itself with technical propriety under a huge variety of conditions. It burbles along on a 4 to 1 gear with its throttle almost shut, or it bellows along on the same gear ratio at a mile a minute; again, it sometimes has to face a climb at a very low road speed, with the revs. mounting up towards 2,500 or even 3,000 on a gear of perhaps 12 to 1.

Patience.

PERSONALLY, I fully expect to see the aero engine paraphrased into a motor cycle engine ultimately. But I shall not be at all disappointed if some of the early peace engines closely resemble the pre-war engines. The two types of engine may prove to be less closely related than some of us fancy, and designers must not be blamed if they avoid headlong recklessness. I hope one or two of the best brains are almost ready to offer us the new type of engine, but if they are not we can wait.



LUBRICATION.

Some Further Notes on Internal Cooling

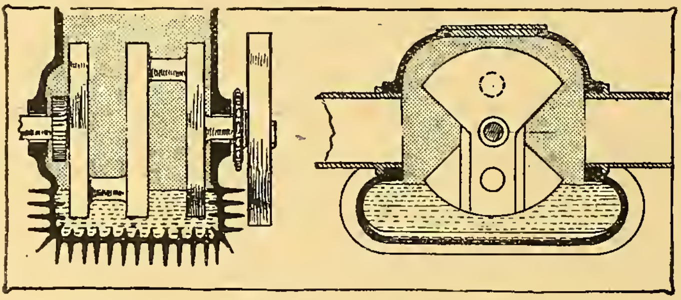
By "Chinook."

SOME months ago the writer dealt fairly fully with the subject of internal cooling as applied to the Maybach (Zeppelin) and various aero-engines of to-day—its desirable effect as regards lubrication, and the possibility of its application to motor cycle engines. Following the article came various suggestions from readers, some good, some unpractical, and others obviously impossible. The subject, however, is one so brimful of interest, and appears to have received so little attention from motor cycle engineers, that it may be worth while to review the proposition once again—though this time from a somewhat different standpoint.

One thing is certain—that engine design has reached a pitch where considerable revision as regards lubrication is essential. Hitherto we have been content to pump a predetermined quantity of oil into the crank case and allow it to stew there till the engine demanded a revivifying of the weakened supply, but with the high revving, highly efficient engines of to-day something better is required than this system of periodical cooling down the old and fatigued supply by a fresh charge. If we are to evade red-hot pistons and ensure longevity for the engine, then we must make sure that the oil in the crank case is always sufficiently fresh and cool to do its work.

Defects of Mechanical Lubrication.

A few days ago I was discussing the problem of lubrication with one of the most practical motor cycle engine designers of the day, but though on many points we agreed whole-heartedly, others brought forth a very natural diversity of opinion. One point of agreement was that mechanical lubrication, as employed on most American machines to-day, has not yet reached a point of perfection to warrant its general adoption by British manufacturers. The concurrent opinion was that, if a rider is too big an ass to be entrusted with the use of a hand pump, then assuredly the mechanical oil pump will prove beyond him. In both cases—though less so with the hand pump—he will alternatively starve and overoil his engine, and until mechanical lubrication reaches a pitch whereby the likelihood of error is much reduced, it has very little to recommend it.



A suggested design for an air-cooled oil sump of large capacity by means of which the oil would be prevented from attaining too high a temperature.

To quote a single instance set forth by my companion. His riding—done on an American machine with mechanical lubrication—is chiefly of the to and from home variety. One way it is all up hill, and the other all down, and he states that for weeks past he has been attempting to obtain that nicety of adjustment to suit the round trip. Once or twice he has very nearly hit the mark, then a change in the weather or a new brand of oil has upset his calculations and necessitated starting from the beginning again. The result is that he has now set the mechanical pump to feed a very small proportion of the oil necessary, and he makes up the deficiency by the use of the hand pump.

Visible Feed and Drying Up.

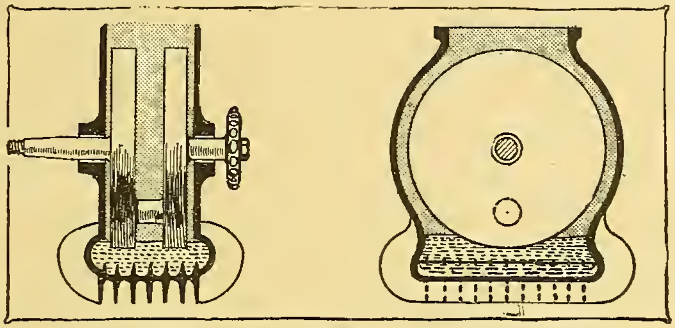
It would seem that the only mechanical system which recommends itself is one that has not yet been adopted, though the excellent system employed on the 3 h.p. Enfield comes very near it—namely, a system by which the oil from the pump passes through a sight feed in the tank, and is instantly adjustable by means of a screw, in the same manner as an ordinary drip feed. We should then be able to regulate the supply instantaneously and in exact accordance with immediate requirements, and on frosty mornings we should experience no qualms as to whether the engine was getting its proper supply. An ordinary hand pump would be incorporated, of course, for there is no doubt that an engine appreciates a periodical deluge of oil.

Let us for a moment, however, drop the subject of pumps. There are certain highly-efficient engines on the road that can be made to "dry up" even though flooded with oil. The necessary conditions are a long up grade, a following wind, and an open throttle. It is generally thought that an engine cannot "dry up" so long as there is sufficient oil in the crank case, but as a matter of fact I know of no small twin—especially among the "flats"—which will not give these results if new and slightly on the stiff side. It may take fully an hour's riding ere the critical period is reached, dependent on the fit of the pistons and the quality of the oil used, and this state of affairs proves one point pretty conclusively.

brication.—

is simply that the oil imprisoned in the crank case, bjected probably to a partial vacuum, has nothing do but to collect more and more heat till it attains temperature at which its viscosity is something akin that of paraffin—*i.e.*, it is too hot to lubricate, with e resultant “ drying up.”

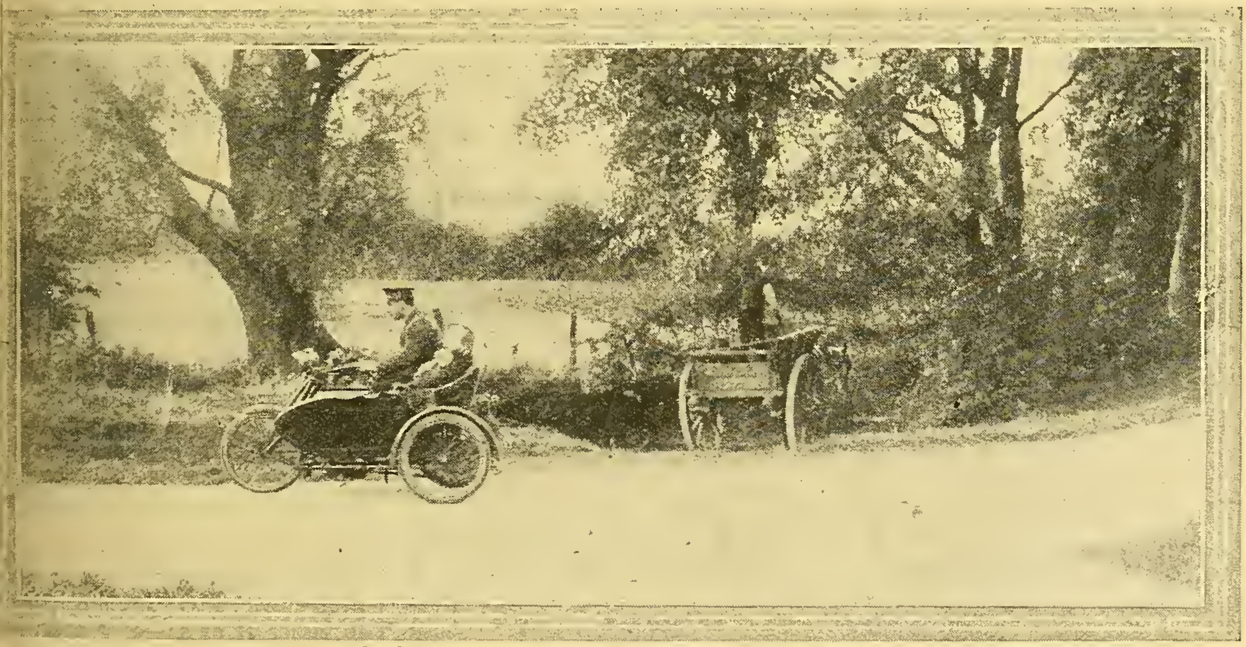
In the four-cylinder Henderson engine a half-arted attempt is made at retaining the crank case l at a moderately low temperature by the employ-ent of cooling fins on the crank case itself, and the enderson designer is to be complimented, if not for oroughly attaining his oject, at any rate for ving the heart for aking a pretence at it. e want the same thing a much larger and ore extensive scale. et us have good deep as into which the oil n gravitate, not only e outside of the sump, it also the inside being rrugated. If the gine can be internally oled, so much the tter, but at all events some attempt should at least made to cool the sump if the engine is to wear well d be economical in oil. In present-day design oil mps are usually of very limited capacity, and generlly their exterior is thickly caked with mud, which nders what little radiation might take place.



A sump of large size designed for an inside flywheel engine.

The capacity of the sump is an exceedingly imrtant point. By employing a sump of large pacity not only is the radiating surface naturally creased, but the reserve of oil permits indiscretions the manipulating of the supply which, with a small sump, at once lead either to drying up or a smoky exhaust. What I mean is that a single charge added to the contents of a sump already containing, say, one pint, makes little difference to the oil level, while with a small sump an equivalent dose might immediately mean a sooted plug; and similarly, having a large reserve, no harm is done if one inadvertently omits to give the desirable charge. Thus, having started the journey with the supply at the correct level, one can employ more or less haphazard methods for many miles to come.

Personally, I am all in for the hand pump, large, air-cooled sump, and mechanical pump for circulating and distributing the oil. The hand pump is the zenith of simplicity, and given oil sumps of sensible design there should be no difficulty in ascertaining that the oil is at the correct level before each journey, thus removing the objection of irregularity. It is particularly noticeable that machines provided with diminutive pumps are all of them ticklish as regards oiling, so it would seem that the first step is to redesign our crank case, after which half the difficulties of administering the oil will disappear—whether it be administered mechanically or by hand pump. In adopting these methods we should only be following approved design in car practice, and after all it can be borne in mind that the manner in which the oil is delivered to the engine is of little consequence compared with what is done with it when it gets there.



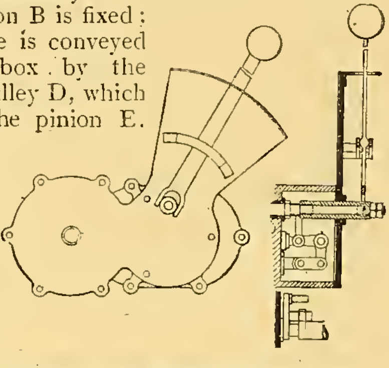
ON LEAVE. The majority of men owning motor cycles who are serving abroad know by now that petrol is obtainable for use whilst on leave by applying to the Controller, 19, Berkeley Street, W. A good tip is to apply in time, and call personally for the permit.

AN ORIGINAL GEAR BOX DESIGN.

Simplicity and the Four-speed Gear.

THE ingenious and compact four-speed gear designs illustrated on this page are the work of Mr. B. Malkin, 123, Lockend Road, Leith. Taking the sectional view at the bottom of this column, it will be seen that the chief merit of the design lies in the small number of pinions employed in obtaining the necessary ratios, thus cutting down cost of manufacture and tending in the direction of general simplicity.

The first design may be described as follows: The drive is transmitted to the mainshaft A through a clutch in the usual way. To this shaft the pinion B is fixed; similarly, the drive is conveyed from the gear box by the sprocket or belt pulley D, which is integral with the pinion E. The pinion F, lying midway between these two mainshaft pinions, is mounted on a splined or square sleeve running free on the mainshaft. On this sleeve are mounted the dog clutches L and M.



Sectional and elevation drawings of the gear control of four-speed gear box.

The pinions G, H, and K are free to rotate independently on the layshaft, but either or both G and K may be connected to H by the dog clutches O and P on respective sides of H.

The dog clutches L and P are operated together, so that either E may be connected to F or G to H, but not simultaneously. The same applies to the dog clutches O and M, which respectively can bring the pinions B, F, K, and H into communication.

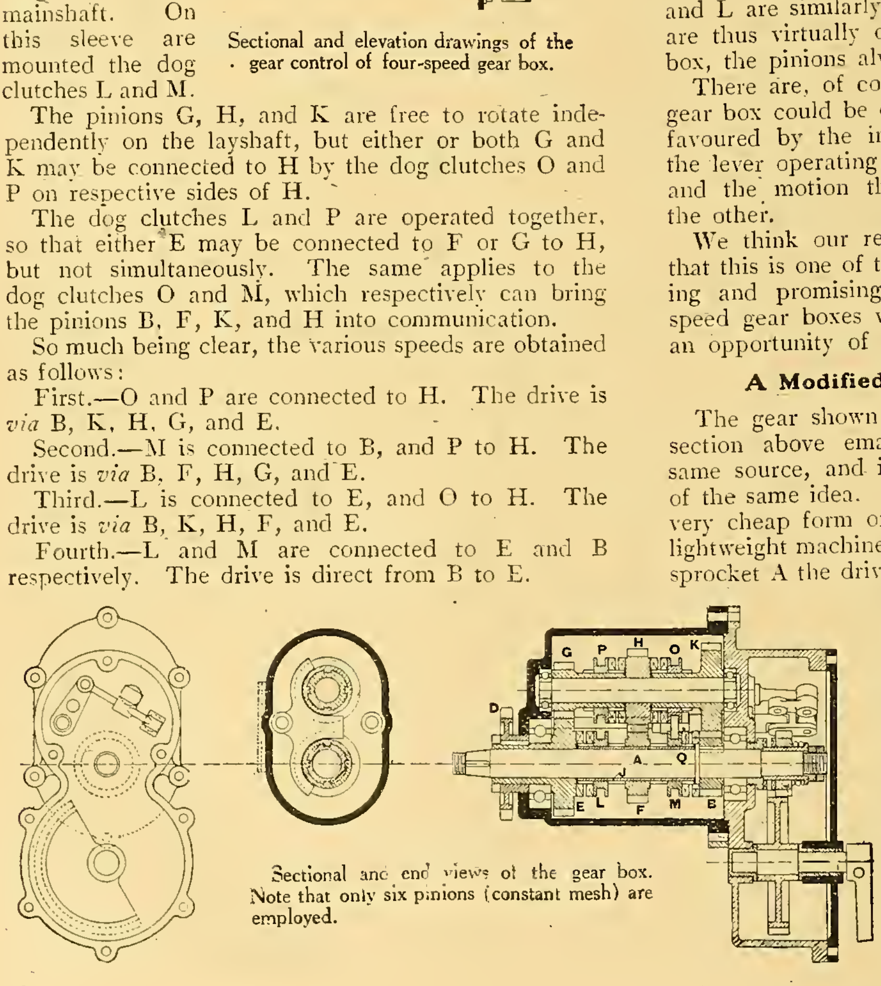
So much being clear, the various speeds are obtained as follows:

First.—O and P are connected to H. The drive is *via* B, K, H, G, and E.

Second.—M is connected to B, and P to H. The drive is *via* B, F, H, G, and E.

Third.—L is connected to E, and O to H. The drive is *via* B, K, H, F, and E.

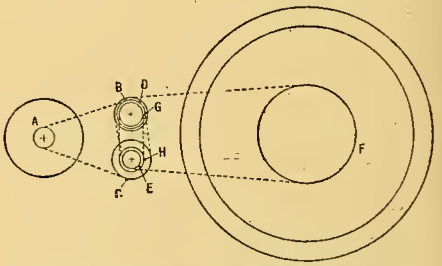
Fourth.—L and M are connected to E and B respectively. The drive is direct from B to E.



Sectional and end views of the gear box. Note that only six pinions (constant mesh) are employed.

Referring to the gear ratios obtainable, the invento assumes the following:

Number of teeth on pinion	G	14.
,, ,, ,, ,, ,,	E	28.
,, ,, ,, ,, ,,	H	21.
,, ,, ,, ,, ,,	F	21.
,, ,, ,, ,, ,,	B	18.
,, ,, ,, ,, ,,	K	24.



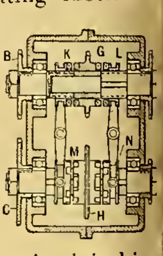
Showing one form of application for use on lightweights, three chains being employed in obtaining the four gears.

This will give proportions of 4½, 6, 9, and 12 to 1

The dog clutches O and M are operated by mean of the double fork Q, fixed to a sliding bar, while and L are similarly operated by another bar. Ther are thus virtually only two sliding parts in the gea box, the pinions always being in mesh.

There are, of course, numerous ways in which th gear box could be operated, but a car gate change favoured by the inventor, the oscillating motion the lever operating one sliding bar, and the motion through the gate the other.

We think our readers will agree that this is one of the most interesting and promising types of four-speed gear boxes we have yet had an opportunity of examining.



A chain-driver box embodying th same principles.

A Modified Design.

The gear shown in diagram and section above emanates from the same source, and is a modification of the same idea. In this the inventor is aiming at very cheap form of gear, intended for application lightweight machines and cycle cars. From the engir sprocket A the driving chain passes over the sprocke B and C mounted on the gear bo The rear chain passes from tl two sprockets B and E to tl sprocket F of the rear wheel. I side the gear box are the tw sprockets G and H, connected l chains of a suitable type (gea may be used in preference sprockets). The sprockets B, and D are free to rotate ind pendently, but G can be connect to either B or D—as already d scribed in the previous inventi —by means of dog clutches (K a L). Similarly, the sprockets

Still the Motor Cycle of Supreme Reliability.

Reliability supremacy, which the Ariel secured by its masterly performances in open contests, it holds more firmly than ever to-day.

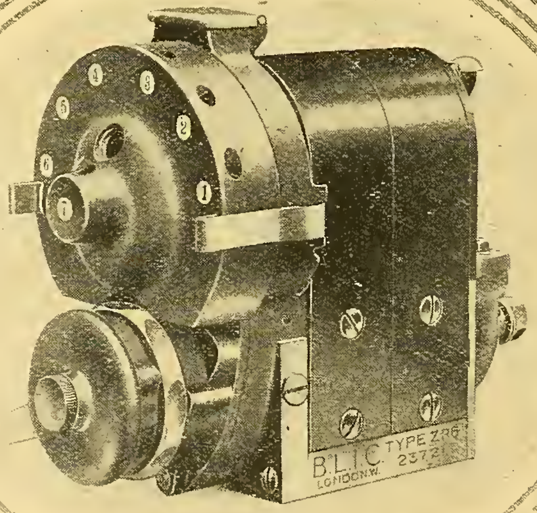
THE BRITISH LIGHTING & IGNITION Co. LTD.

MODERN WARFARE is the supreme test of all mechanism—whatever the circumstances, it *must not* fail. And under these strenuous conditions the "B.L.I.C." Magneto has fully demonstrated its unrivalled supremacy.

THE BRITISH LIGHTING & IGNITION CO., LTD.
Proprietors: VICKERS, LIMITED.
204, Tottenham Court Road, London, W.1.



ı Original Gear Box Design.—

, and E can be brought into contact by the dog utches M and N. The four gears are obtained as ollow:

.) A, C, H, E, F. | (3.) A, C, H, G, D, F.
.) A, B, G, H, E, F. | (4.) A, B, G, D, F.

It will be seen that the first and fourth gears are irect drive, and the gear box contains only two rockets and four dog clutches. The direct drives can e obtained for second and third by a slight rearrangeent of the sprockets. The operation of the gears could be as shown, or, alternatively, by a system similar to that described in the first invention.

This latter gear box does not appeal to us as being so highly practical as the first, but the inventor considers that the difficulties it suggests are more conspicuous on paper than they would be in practice. It may be pointed out that in machinery of all varieties chains are arranged as shown in this idea, and that experience proves that, provided the chains are in proper alignment, they are seldom a cause of trouble.

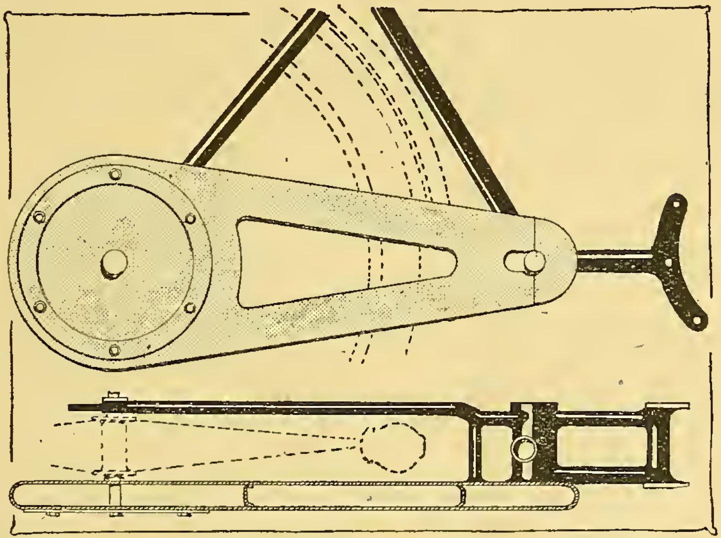
We certainly think that Mr. Malkin is to be complimented on these two interesting designs.

A Chain Case Integral with the Frame.

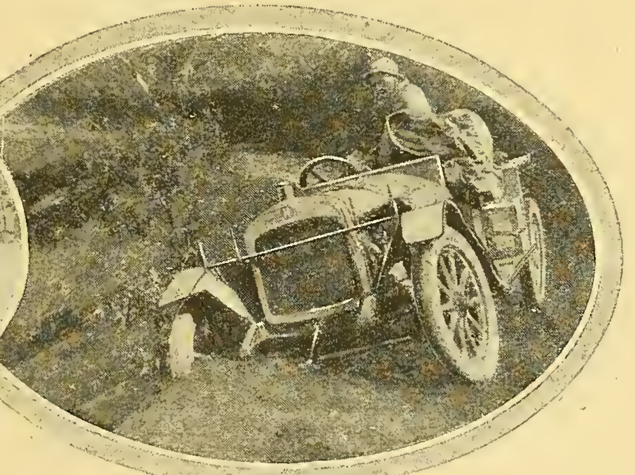
THE Limana, a rather revolutionary patented esign of chain proctor, can be built ito or built up with ie frame of cycles of ormal diamond type esign. Instead of eing an accessory, ie chain case beomes an integral and ssential part of the ame, taking the place f the chain stay tube n whichever side of ie machine the final rive is situated.

It consists of a ctilinear section ollow U tube bent ito an "oblongated" orseshoe or magnet iape, the open ends f which are covered ı by a detachable cap, semi-circular in shape, as ie designs make clear. When, too, the bend of the horseshoe is filled up and provided with an inspection cover and two side panels added it does not require much more to make a totally-enclosed oil bath and case for chain and sprockets.

This is briefly the idea as patented, and its adaptation to varying models is a matter for its builders. The drawings will be more enlightening than any amount of explanation, but it should be noted that the Limana confers extra rigidity to the frame where it most needs it, is noiseless, and an absolute protection to the transmission. It may also be used for the final drive of belts. Removal of the wheel is easy.



A unique design for a chain case. The idea, which is patented, was sent to us by C. S. Harvey, Como, Italy.

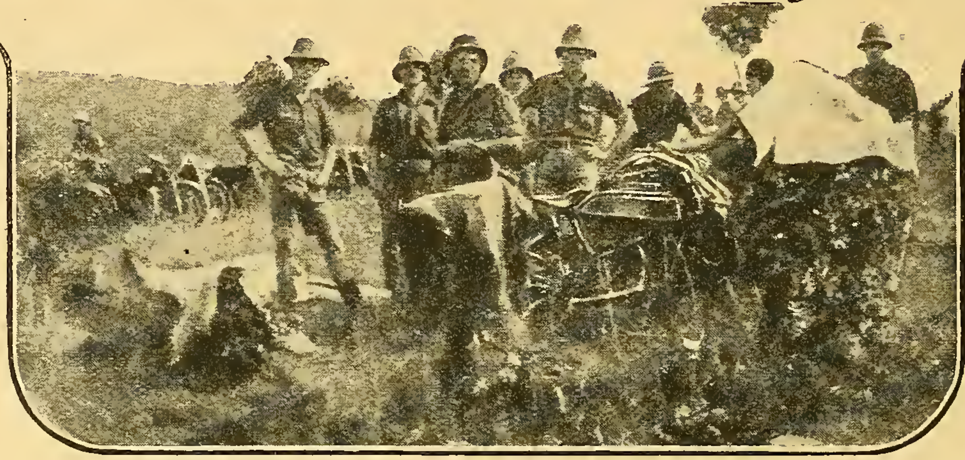


WITH THE BRITISH FORCES IN NYASALAND (See next page).

Treking along the road made by the engineers. Many miles of such roads were laid through dense bush country under bad climatic conditions.

A transport car that had a narrow shave on a hairpin bend; had it gone right over it would have rolled 1,000 feet down into the gulley below.

With the British Forces in Nyasaland.



A group of motor cyclists in the bush of Nyasaland. In the background may be seen a few of the machines, chiefly B.S.A.'s.

How a Small Body of the S.A. Motor Cyclist Corps bravely held back an Attack on the Lines of Communication.

THE following details of the campaign with the S.A.M.C.C. were sent to us by Lt. E. W. Mathieson (Nyasaland Field Forces), and convey a good idea of the difficulties motor cyclists had to encounter in the wild districts of East Africa:

"Not having seen anything recently about the S.A.M.C.C. in *The Motor Cycle*, I thought it was up to me to supply a few lines. [An article appeared recently illustrating the campaign in German East Africa.—Ed.]

"Very few people, especially Oversea folk, know that such a corps exists, and I have every reason to believe that we are the first of its kind ever put in the field.

"At the beginning of the campaign we numbered 300 strong, but in consequence of the privations and bad conditions endured we have dwindled down to forty—all that is left of the first 300. Of course, we have been receiving reinforcements all the time, but even now we are not up to half the original number.

"We have been over eighteen months in this country without any break at all. Originally we were with the Northern Forces and were in the big push, during which 75% of the corps were knocked out with sickness, etc.

Bluffing the Huns.

"In the rush on the Central Railway we were among the first to reach the goal. The problem was to join up with the Southern Force, and naturally we motor cyclists being so mobile were the first to shake hands with the other force, both they and our main body having worked from either side of East Africa.

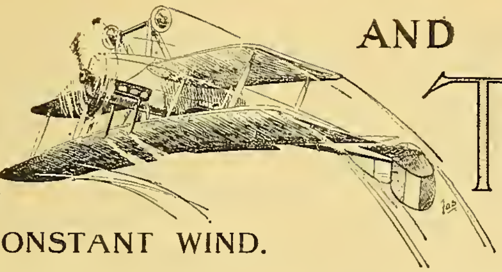
"It was here that our corps played a marvellous game of bluff. The Huns informed us that they were going to recapture the town. Motor cyclist patrols were buzzing in every direction, and the men were doing thirteen days on three days' rations. Fortunately a little food was to be obtained on the land. Whichever direction the Huns advanced they were met by cyclists; every path and track was utilised by us, and when they forced our people to retire here they next found that others were again on each flank behind them, and so after a few weeks they gave up the idea of recapturing the town. Prisoners that were taken afterwards showed a great interest in the corps, and informed us that they made our strength out to be 2,000. I suppose you will hardly credit it, but there were no more than 250 of us in the place. Owing to the corps being able to move so quickly, and consequently being here one day and there the next, they could not make out our strength at all.

Disappointment.

"We pushed on, and when the rainy season came we were so far forward that the Northern Force we were with left us behind and we were promptly taken over by the Southern Force. Soon after the Northern Forces went home on leave—what a disappointment it was to us, for had we not been so far forward we would have shared the same pleasure of a well deserved run home. It was with the Southern Force that the corps did another fine piece of work. The Huns were just about to cut our lines of communication when our General sent us forward to hold them back. Our numbers were exceedingly small, but we were quickly despatched, and forty of us held back over 500 until reinforcements came up and so saved the situation. Our casualties were heavy, but apparently our luck was in, and the way the General afterwards thanked the men made each one who took part in the scrap feel a hero on his own.

"We are still up here and would not be surprised to see the last of the campaign. Of course, all readers of the 'Blue 'Un' know that we are mounted on B.S.A. machines, and we cannot say enough for them; in fact, most of the men would be afraid to try any other make in this country."

FLYING FACTS AND THEORIES



THE INCONSTANT WIND.

By W. G. ASTON, A.M.I.A.E.

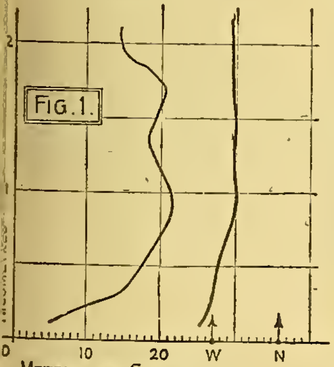
REVERTING once more to the question of turning "up" and "down" wind (after this article I am in hopes of getting clear away to another sject), there is one point that has not, singularly eugh, been brought up by any correspondents, but jtifies none the less a certain amount of consideratin, although its influence upon the "up" and ‘lown" question is comparatively slight.

The primary assumption which I made when going io the matter of relative motion was that the speed o the wind was constant. In actual practice this is srcely ever the case for more than a second or two tgether; indeed, its variations both in respect of sength and direction are proverbial. It may be not thout interest, therefore, to glance into the inditions which such wind changes promote. The amount o energy that is dissipated by gusts and other wind eects is perfectly amazing, and it is almost incredible tht it is all derived from comparatively small differences in local temperatures. If it could be eectively tapped the supply of power in, say, a cubic ile of air on an average day would be enormous, en disregarding the bodily motion of the volume as a whole, and only taking advantage of the small sts. Wind variations are of every conceivable kind, om the very big changes in speed to the very small anges in direction. For the moment, however, we ll neglect the gusts and consider only the larger ects.

Wind Charts.

Wind is a relative movement between the earth and s surrounding atmosphere, and as a consequence the nditions are exactly analogous to those of any other dy moving through a fluid. Where the fluid and e body meet friction takes place, the result being a ndency for the fluid to stick to the body, and in consequence to slow down. One would expect, therefore, s is the case, that near the ground the wind speed tends to be generally less than at a fair altitude, and also that, owing to differences in earth configuration, there is more likelihood of the direction being definite and steady high up than at ground level. Also at very high altitudes the wind will have a most decided tendency to be very constant indeed.

FIG. 1.



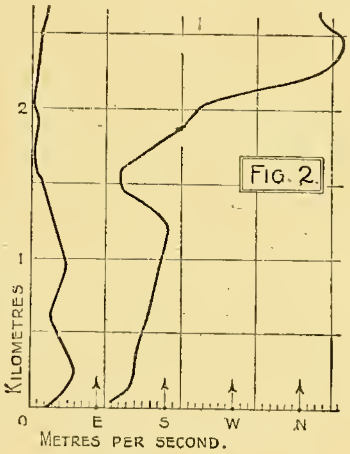
Wind of variable speed.

In figs. 1 and 2 are given actual wind charts, which show to what extent these variations occur. Fig. 1 is a striking, though not very unusual chart, whilst fig. 2 is more interesting, because it shows what *can* happen, even if a rare occurrence. The height in kilometres is shown on the vertical scale; on the horizontal scale are shown both wind speed in metres per second and compass bearings. In each chart the left-hand graph relates to speed and right-hand to direction. With regard to the latter, the point marked N (North) is zero, and each square represents 10° of inclination away from that point. Thus above 1,000 metres of altitude the wind charted in fig. 1 has a fairly constant direction pretty nearly west-north-west, but with a slight tendency to west, which becomes more marked as the altitude is increased.

This figure shows that the biggest speed differences are occurring near the ground; thus, in less than one kilometre of altitude, the difference is about seventeen metres per second; or, roughly, a wind of ten miles an hour at 300 feet becomes at 3,000 feet one of fifty miles an hour. Above this point, however, it tends to slow down again, but by no means steadily.

In fig. 2 the maximum speed differences are much smaller, and the greatest wind is at 600 feet, after which it gradually tails off to a very small figure. But look at the direction variation. Due east at ground level, the wind is nearly due south at a height of $1\frac{1}{4}$ kilometres. Then it goes east again, becoming due south at a little less than two kilometres. After that it goes first due west and then due north, with a final attempt to get west again. In short, inside 8,000 feet it completely boxes the compass!

FIG. 2.



Wind of varying direction.

Wind Gradients.

Now, supposing we take the conditions recorded in fig. 1 and imagine an aeroplane about to start a flight. Neglecting the actual difference in direction, we will say that the wind is steadily from north-west. If we fly north-west we shall as we climb be meeting a wind that continually gets stronger and stronger up to about 3,000 feet. The immediate effect of this will be that

Flying Facts and Theories.—

the aeroplane will climb more rapidly than it would do, *ceteris paribus*, in perfectly calm weather. As it engages each successive layer (as it were) of air, it will momentarily have an increased speed relatively to it. If its ordinary air speed is 100 m.p.h., it will keep this speed constant only so long as the wind itself is constant. If it suddenly strikes (by climbing) a layer of air travelling faster, its air speed will momentarily rise, say, to 101 m.p.h. If it stopped in this layer of wind the air speed would drop back, of course, to 100 m.p.h., but, if it continues to climb, the "wind gradient" goes on helping it by always trying to increase its air speed. This effect, of course, falls off immediately the maximum wind speed is passed. Thus, referring to fig. 1, the climb will be unduly fast up to .9 kilometre; from that point to 1.3 kilometre it will be unduly slow, since now the "wind gradient" is in the opposite direction and the speed is dropping instead of rising. From 1.3 kilometre to 1.7 kilometre the climb, however, will be again accelerated, and then, in turn, diminished up to two kilometres. This is, of course, always provided that the machine retains its N.W. direction. It will get the best climb possible by altering course in accordance with the wind gradient, *i.e.*, by flying N.W. up to .9 kilometre, S.W. from this point up to 1.3 kilometre, then N.W. again up to 1.7 kilometre, and finally S.W. up to two kilometres. If it reverses these tactics it will climb unduly slowly.

Starting from the Ground.

For this reason the climb performed by the same machine varies very much on different days, apart altogether from the help that may be gained from upcurrents. When watching an aeroplane, one always receives the impression that it climbs faster when flying "into" the wind, and this is actually the case when the wind gradient is favourable, as almost always obtains near the ground. If the wind gradient is unfavourable, however, it will climb more quickly by flying *with* the wind and not against it. If the wind were steady and the same speed all the way up the altitude scale, it would make no difference to the rate of climb of the aeroplane in whatever direction its pilot chose to fly, except for the fact that one gets off the ground with a shorter and slower run against the wind. With the wind the run is longer and faster, but, needless to say, lasts the same time.

Sudden Wind Changes.

It will at once be perceived that if the aeroplane gains an advantage from relative speed by climbing in accordance with the wind gradient, it can equally well lose to the same extent when it is descending. Referring to fig. 1 again, if the machine is gliding at its natural speed at .9 kilometre of altitude, and is travelling N.W., then it will find each successive layer of air travelling slower and slower. If it starts gliding at its very minimum speed, it is conceivable that the wind-gradient may cause it to stall, since on striking a lower layer of air the relative air speed may momentarily fall off.

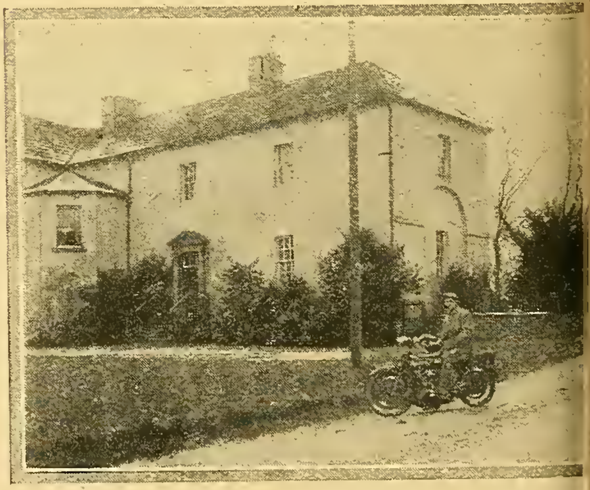
Now it is not only in gliding that an aeroplane loses height. As we have seen, an aeroplane can lose height on a turn, and thus the wind gradient may assist in the reduction of speed, and therefore in th tendency to stall. Imagine a range of mountains lik a wall 2,000 feet high, and a steady wind to be blowing across them. Whilst an aeroplane is 2,010 fee up it is flying relatively to this wind, but if it drops t 1,990 feet it immediately meets with entirely differen conditions. If the wind speed and the aeroplan speed are the same, then the drop of 20ft. (this is very imaginary case) may cause the entire loss of it original relative velocity, so that once below the leve of the top edge of the mountains it will have to do violent nose dive to regain its previous speed in th still air.

Losing Height on a Turn.

A similar state of affairs, though immensely modified, can occur when a machine loses height on turn, and especially near the ground, where, owing t the presence of shielding objects such as trees c houses, or to the configuration of the ground bein such as to promote the formation of surfaces of discontinuity (regions of "dead" air), the wind gradien is liable to be very severe as well as changeable. I is for this reason that any sort of turn near th ground is more or less dangerous, the worst of all bein that in which the speed of the aeroplane is but littl above its stalling speed. With a variable wind, therefore, turning "against" the wind is not necessaril the same as turning "with" the wind, but, as previously pointed out, if the wind is constant in spee and direction the two evolutions are identically th same.

The wind gradient refers only to wind spee But a similar consideration exists in regard to direction. Thus, if as a machine turns the wind als changes in horizontal direction, then the aeroplan may be momentarily either lifted or depressed. Th former will take place if, when the aeroplane is turning, the wind changes and meets it "nose on" o "ahead"; the latter if the wind changes and meets "astern."

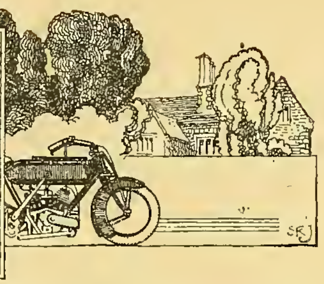
Further effects of gusts will be dealt with in th next article of this series.



The old inn and posting house at Greta Bridge, near Barnard Castle, where Dickens stayed whilst in the North of England. The "snug" used by him can still be pointed out in this interesting place.

MOTOR CYCLE DESIGN

AN ANTICIPATION OF FUTURE DEVELOPMENTS.



ON Tuesday, the 19th inst., Mr. A. G. Pendrell read a very interesting paper before the Coventry Branch of the Institution of Auto-obile Engineers on "Motor Cycles." In this paper Ir. Pendrell dealt very comprehensively with the lead-g features of motor cycle design in the past, and dicated certain lines along which developments might e most profitably directed for post-war enterprise.

The following remarks are entirely taken from his aper, and they are not necessarily to be regarded s expressions of our own opinion.

Design.

The motor car and the push cycle were at first used r pleasure: their practical everyday use came later, nd resulted in an expansion of their market; the same ay be expected to take place with the motor cycle, hich, on the outbreak of war, was just passing be-ond the pleasure stage.

The frame, as the most important part of the design, eeds the fullest attention. Frames at the present me are perhaps the most unsatisfactory and least eveloped part of the machine. Spring frames are s far off as ever, although the attention recently evoted to this subject bears every promise of pro-ucing good results. In such a detail as forks, cycle ractice has been followed far too closely—for in-tance, the practice of gripping the handle-bar stem y means of a slot in the steering stem is very crude, nd it is time a more substantial design was introduced.

As regards wheels, an easily detachable spindle, nabling the tube to be simply inserted with the wheel *n situ*, would be likely to give more satisfaction in ervice, especially on solo mounts, than would the niversal application of an interchangeable wheel, ith the consequent necessity of carrying a spare.

Although engines are continually receiving atten-ion, and alternative types are always being brought orward, the 3½ h.p. single-cylinder of about 560 .c. is undoubtedly the most popular, and is likely to emain so for some time, while such an innovation as he wide application of outside flywheels is not likely o materialise rapidly, if for no other reason than that y placing the flywheels in the crank case the energy hey store is kept closer to the bearings.

The slow running of most engines is bad, this being nainly due to faulty carburetter design, and makers ight advantageously take a few hints from American ractice, in which the maker of the machine also nakes the carburetter or has it made to his designs.

An Extraordinary Statement.

Perhaps the most extraordinary statement made in the paper was on the subject of magnetos. Mr. Pendrell suggested that after the war we should in all probability have to return to German magnetos. His argument was that, while British magnetos are excellent mechanically, they are not quite perfect as regards insulating compound used for the mouldings, and such foreign magnetos as are now available may at the best of times only be regarded as third-rate substitutes for the German article. Also, the English magneto manufacturer would find the question of output one needing his serious attention, as it would seem that the combined English output would scarcely supply Coventry alone. One English firm, recently receiving an order for 300 magnetos from a firm of motor cycle makers, had to order tools and sufficient material for their production!

There is little doubt that the introduction of the clutch and change-speed gear has led to a general reduction in the quality of engine tune. Engines could then be so much more easily started by means of pedals, consequently the clutch indirectly necessitated a variable-speed gear, which again made engine tune of less importance than it had been previously. As regards the type of gear box, the sliding pinion type is likely to give most satisfactory service in practice, and the constant mesh pinion type is always likely to remain a second in point of number. The gear box also may account for the increased noise of the present day motor cycles over those of a few years ago. Gear boxes make a noise, and the efficiency of the silencer has been deliberately reduced so as to drown the noise of the gear box!

Front brakes and mudguards are subjects now receiving some attention in the press, and there is no doubt that too much airing cannot be given them. Probably the fitting of good size leg-guards is the only possible solution of the mudguarding question.

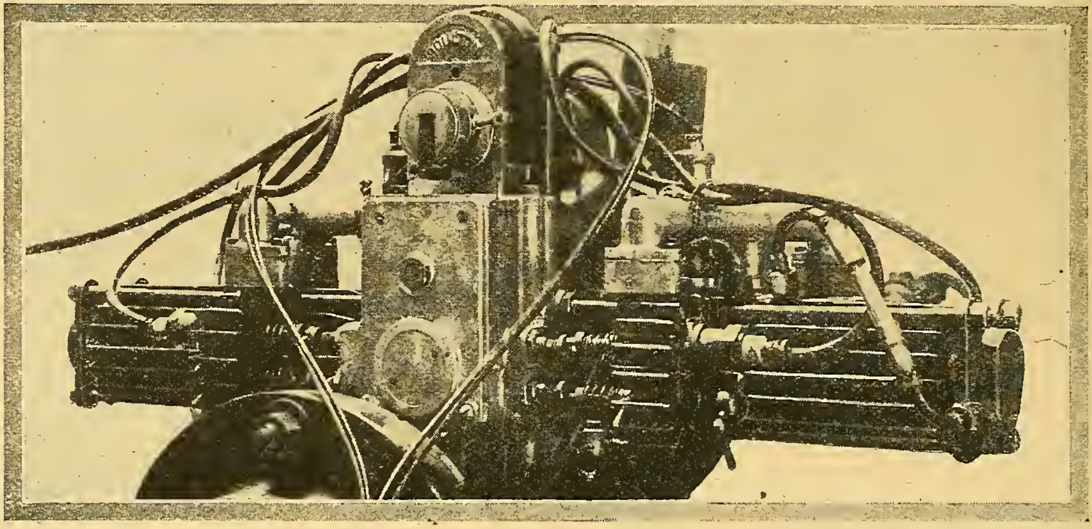
T.T. Suggestions.

The T.T. race is a matter that might profitably be considered, and is one that lays itself open for some improvements. For instance, instead of serving to lionise one machine and one rider, the winner, it would probably be of more real use to the trade were the machines finally placed in classes according to their speed, the machines in the various classes being arranged in alphabetical order. There would be a first class of 50 m.p.h. and over, second class of 45 to 50 m.p.h., and so on, the speeds given being the average speed for the whole course. The character of the race has been entirely altered from that originally intended, and a revision of this intention would be for the good of all concerned.

Everyone agrees that present day machines are far too heavy, but weight cutting must certainly not be done at the expense of strength, consequently the only alternative is the use of high-class materials and designs that allow of less material being used.

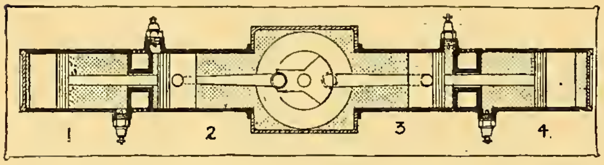
THE FROST TANDEM FOUR-CYLINDER.

A British Engine of Remarkable Design, constituting a Power Unit weighing 70 lb., and developing 23 h.p.



The clean line appearance, due to the employment of horizontal fins, is somewhat marred by the temporary fittings for test purposes. The overall length is not so considerable as might be supposed. The capacity of the engine is 790 c.c.

When speaking of four-cylinder motor cycle engines one's thoughts are apt to fly at once to the production of our American Ally as embodied in the Henderson and Pierce, or again to the Belgian F.N.; and good examples they are without a doubt. For some time there have been rumours that British manufacturers are experimenting with the four-cylinder, and we are now able to give details of one of these engines. This is to be known as the Frost, and it is now in an advanced experimental stage at the works of the Frost Patent Engine Syndicate, Ltd., Wolverhampton.



A diagram showing the action of the Frost engine. The firing spaces are indicated by the plug positions. A two-throw crank set at 180° is employed.

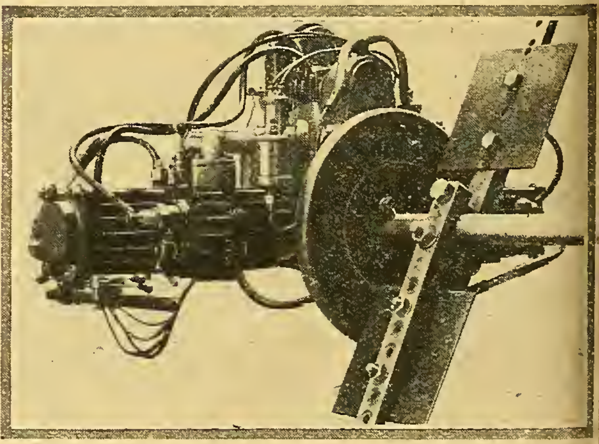
In appearance it may be easily mistaken for a flat twin, a little longer than usual, it is true, but it is in effect a horizontally opposed four-cylinder with two cylinders placed end to end on each side of the crank case.

Its action may be seen on referring to the diagram herewith. The pistons are connected in pairs by a rigid connecting rod sliding in a gland; on each side of this gland are the firing spaces or combustion "heads." The inner pistons only have gudgeon pins and connecting rods, and the crankshaft is of the usual two-throw type. With No. 1 cylinder in compression, No. 2 is at the end of its inlet stroke, about to compress; No. 3 is at the commencement of the exhaust stroke, and No. 4 is completing the exhaust stroke.

The valve pockets are placed alternately two on each side, and the valves are operated by simple cams, rockers and spur wheels driven from the shaft as in usual practice.

Lubrication and Cooling.

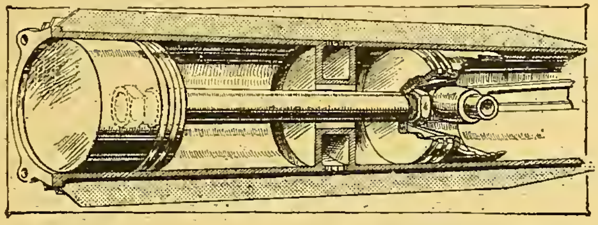
These are points which occur at once on considering any tandem type of engine, but here we have the two compression spaces separated by a hollow air-cooled gland lubricated by forced feed. There is also a novel form of internal cooling embodied



The Frost engine under test, a fan brake being employed to provide the load. The heavy outside flywheel should be noted.

The Frost Tandem Four-cylinder.—

throughout the engine. For the present we are not at liberty to say more than that it is simple, automatic, and very efficient; in fact, in the early experiments it was found to err on the cool side, and certain dimensions were varied to correct this unexpected fault. Tangible evidence of its very cool running was afforded when, after a five minutes' run at high speed, we were able to bear our hands firmly on the outer cylinder cover plates, and even around the firing spaces it was not unduly hot.



A sectional view of one pair of cylinders, showing the air-cooled gland between them.

Horse-power and Weight

Now as to power. The engine at present is on the test bench, and we were able to see it in action with a fan brake dynamometer. Each cylinder is 60 mm. bore × 70 mm. stroke (this capacity is slightly reduced by the central rigid connecting rod), the total capacity is 790 c.c. At 2,500 revolutions it developed about 14 h.p., and at 3,000 it had jumped to no less than 23 h.p. Some engine without a doubt! This without special tuning and under the handicap of faulty carburation, which was difficult to regulate with two separately-controlled Amac carburetters. Naturally, at such high speeds it showed a little vibration, but it was very slight.

Weight per horse-power is an important point, and as the total weight of the unit may be given as 70 to 80 lb., it works out at about 3½ lb. per h.p. at its best speed; this may be further improved as developments proceed, but it is light enough for motor cycle purposes as it is.

Other Questions.

Petrol and oil consumption is not yet ascertained, but it should compare favourably with other types of four-cylinder machines. The overall length may be a drawback for some purposes, but the frames of several models are being designed at between 60in. and 70in. wheelbase; it is also proposed to utilise it crosswise in the frame of a three-wheeler of the Morgan type. The cost of production is remarkably low, there being only a simple crankshaft, a small crank case, two connecting rods, and a minimum of machining in the cylinders and valve pockets.

For test purposes the current is supplied by a four-cylinder Boulton magneto—another interesting Wolverhampton product.

Certainly it is a remarkable engine, and one which promises great things in the future, but it is of such an unusual design that one hesitates to offer any criticism at present. Its behaviour on the road will give more definite information, and no doubt will expose some faults, but so original a designer should be capable of countering any reasonable defect, and we look forward to its progress with considerable confidence.

Motor Users, Producers, and Distributers.

The First Steps towards the Formation of the Motorists' United Council,

A MEETING of the United Council of Motor Users, Producers, and Distributers, in its provisional form, was held on Tuesday, February 12th, at the Carlton Hotel. The chair was occupied by Mr. E. Manville. The terms of reference of the Council had been defined at a previous meeting, substantially as follow:

(1.) To ascertain to what degree it is possible for motor users, producers, and distributers to arrive at complete or substantial agreement as regards laws and legislative measures advantageous or disadvantageous to the interests represented upon the Council.

(2.) To use the united influence of the interests represented upon the Council with a view to securing or checking legislation in accordance with the decisions reached under Clause 1.

(3.) In respect of legislation, kindred matters and technical questions in relation thereto, to use its influence to discourage any organisation from acting in a manner calculated to impede the policy, or to injure the interests of those concerned, and to encourage united action and mutual support.

Up to the present eleven recognised organisations have either elected representatives to serve on the Council, or have signified their desire to do so. It has been unanimously resolved that the Council should not allow lack of support from the Committee of any one organisation to delay the inauguration of an active programme.

It has been unanimously determined that the proportional voting power of the three groups of which the Council is formed shall be as follows: Users 24, producers 12, distributers 8.

Also, that the Council, as such, shall not take public action on any matter except as the result of a unanimous resolution.

The Council has taken powers to constitute committees to consider and report upon specific subjects.

A letter and questionnaire will be sent out at an early date with a view to ascertaining the opinions of members of both Houses of Parliament as regards a number of questions of policy which will come before the Council for consideration at an early date.

The officers of the Council will be elected at the next meeting, at which further steps will also be taken to determine the exact allocation of votes to the various bodies coming within the three main groups, the aggregate voting power of which has been already settled, as stated, so as to give the predominance to users of motor vehicles of all kinds.

Hon. sec. (*pro tem.*) Mr. Horace Wyatt, 39, St. James's Street, London, S.W.1.

CURRENT CHAT

Time to Light Lamps

Greenwich Time.

Feb. 21st	... ...	5.53 p.m.
„ 23rd	... ...	5.57 „
„ 25th	... ...	6.0 „
„ 27th	... ...	6.3 „

National War Funds.

The National Relief Fund (distributed £3,783,657)	£6,331,636	0	0
British Red Cross	9,097,823	0	0
Tobacco Fund	148,592	0	0

An 8,000 Feet Climb in Winter.

A rider of an Indian made a new winter record recently by climbing 8,000 feet up Mount Hood, Main, U.S.A.

Drivers Wanted.

Volunteer motor drivers who will undertake duty one night each week in the London district are wanted urgently. Apply, 225, Oxford Street, London, W.

Motorists' Associations.

Whether existing associations justify their existence or not may be open to discussion, and many people seem ready to argue that they do not. Whatever the ultimate result of this discussion may be, however, there seems little unwillingness to the formation of fresh bodies.

A Protection Association.

A letter appears in our Correspondence columns this week on a new association.

Harley-Davidsons for Meat Distribution.

Two Harley-Davidson sidecarrier outfits are being employed daily in connection with a meat distribution scheme in the Greenwich, Lewisham, and Lee district. Long, open boxes are used, designed to carry a whole side of sheep. The service is being run by contract by the local agent.

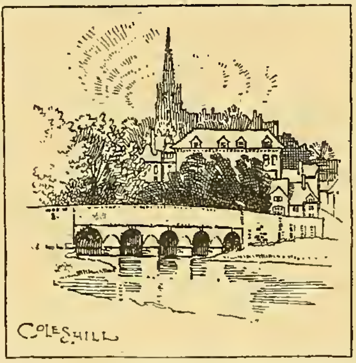
Holland's Supply of Motor Spirit.

We recently had a note to the effect that the fuel situation in Holland was even worse than that here. Holland, however, has partially overcome her difficulty by a recent arrangement with Austria-Hungary, by which she will receive a fair amount of fuel regularly. What Austria is to get in return is not made clear in the announcement of this arrangement.

Remarks on Clutches.

Any reader whose interest in the question of clutch design is of a more than purely popular nature will be well advised to read the article on this subject appearing in *The Automobile Engineer* for February.

As is always the case with articles in this paper, it is well written, and is by a man who has a complete grasp of his subject, both in practice and in theory. No motorist or motor cyclist is likely to read the article without adding very considerably to his knowledge on a subject that is now a matter for considerable attention on the part of designers and manufacturers.



A Novel Four-cylinder.

The new four-cylinder which we describe this week is named the Frost, but, despite the fact that its cooling properties are considerable, it is likely to prove anything but a "frost."

Another A.C.U. Victory.

An A.C.U. member was summoned at Weston-super-Mare recently for the illegal use of petrol. As the result of the defence conducted by the A.C.U. solicitor, the case was dismissed, and some twenty other summonses of a similar nature that were waiting to be heard were cancelled at the same time.

The A.S.E. and their Motor Cycles.

In some of the large munition works, we are informed that the members of the A.S.E. are still allowed to use their machines for travelling to and from their work. In other districts, however, many workers who had really good grounds for using their machines for this purpose have been heavily fined for travelling by motor cycle.

Special Features

AN ORIGINAL GEAR BOX.
A BRITISH TANDEM FOUR-CYLINDER.
LUBRICATION.

Petrol and Gas Licences.

Motor cyclists who consider they are entitled to a petrol or gas licence, and have been unsuccessful in obtaining one, should apply to the Secretary, Auto Cycle Union, 83, Pall Mall, S.W.1.

The Air Force Uniform.

Speculation has long been rife as to what the new Air Force uniform is to be. We hear now that the uniform is khaki after all, very much like the ordinary Service tunic. Rank badges are after Naval style—rings round the cuffs. Blue is to be adopted, so rumour says, *after* the war.

Price of Paraffins Controlled.

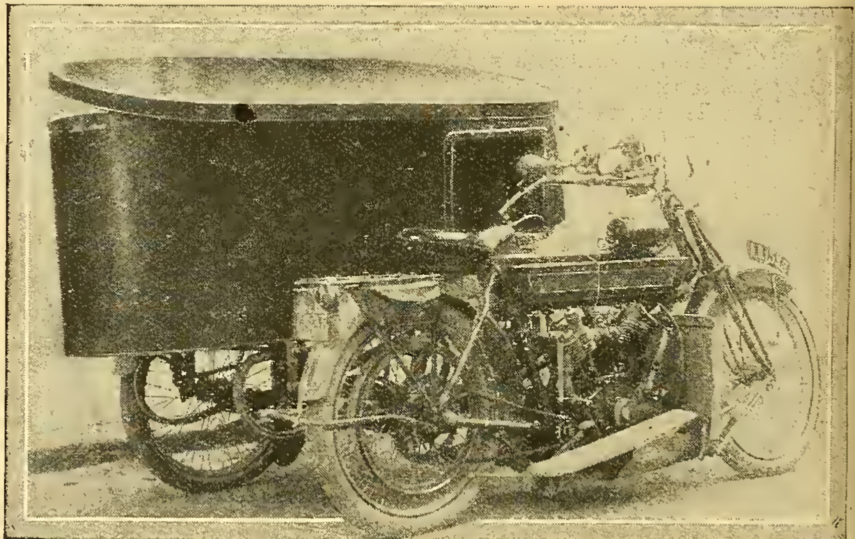
By a recent Order the price of paraffin to the consumer is to be not more than 5d. per gallon more than that charged to the retailer. In the case of lamp oil the amount is limited to 4d. In both cases the profit made by the retailer must not exceed 15% of the wholesale price.

Use of Gas.

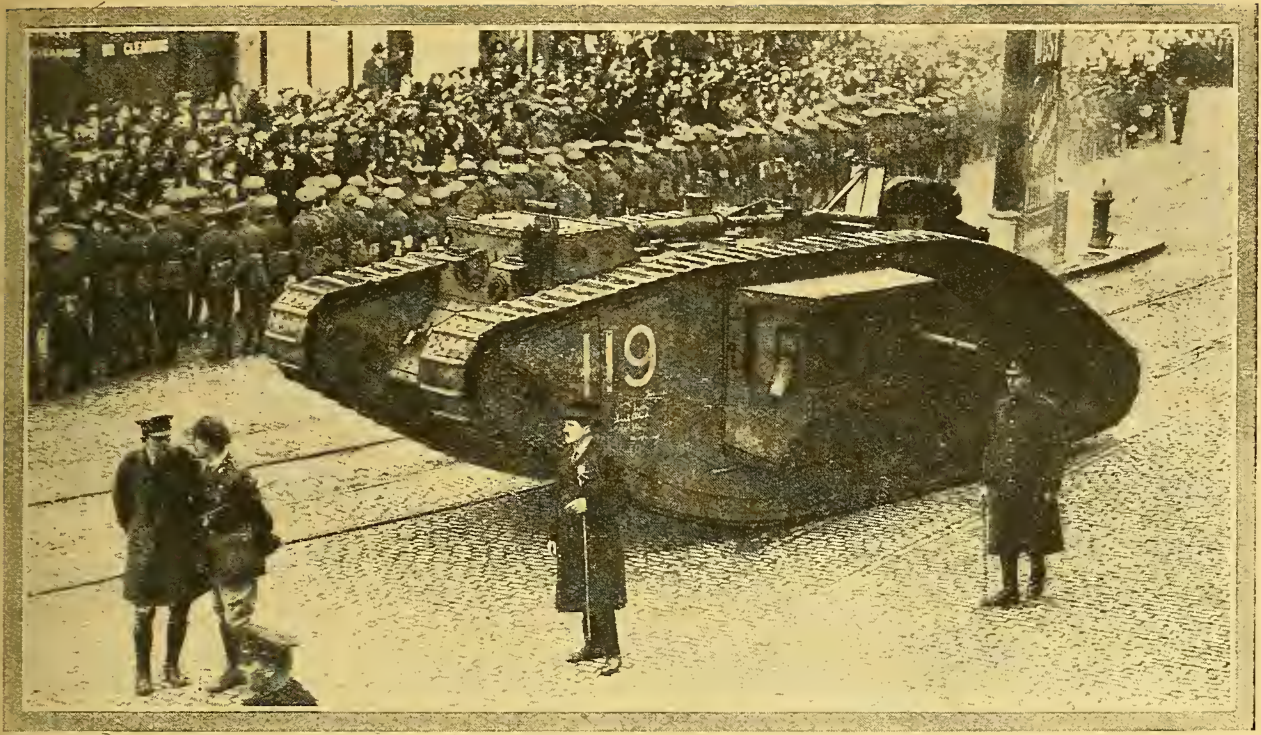
Only 4% of deliveries of gas bags to date have been to private motorists, and 4,500 commercial vehicles have been already equipped for gas, the result being a saving in petrol consumption of approximately 3,000,000 gallons annually.

Extensions.

Orders for equipment for some 2,500 more vehicles are already in hand.



An Enfield sidecarrier used by a baker for delivery of bread. Mr. H. Walmsley, Camborne, says the outfit has been in use every business day for three years. A feature is the commodious flour bin which replaces the ordinary sidecar body.



THE TANK BANK.

The travelling "War Bond" Tank which made its appearance in Coventry last week. Externally the Tanks are familiar to most people, although they still create great interest in the towns they visit.

Cycle and Motor Trades Benevolent Fund.

This is going strong.

The Last Meeting.

At the last meeting, held on January 31st, applications for election were received from 44 members and 196 subscribers.

And the Next.

This will be held on February 28th, at 4 p.m., at 154, Clerkenwell Road, and everything points to a further report of continuous growth being available.

The New President.

The new president of the council is Sir Charles Wakefield, who expressed his pleasure at the evidence of the good work performed by the Fund.

The Motor Cycle Police.

The police in Portland, Oregon, U.S.A., are using motor cycles, and the policemen motor cyclists have a pretty severe course of training to go through in the course of their careers. A correspondent who was present at one of these examinations reports that they had to take part in a slow race, a speed test, and a starting competition, in which they had to stand by their machines and see who could the most quickly get off the mark. Starting the engine first and getting under way by means of the clutch was not allowed. This was followed by a "trouble" test, in which each man had to locate the source of trouble in a machine which had been put out of order and then get it into working condition again. In addition to the actual riding and mechanical test, examination papers had to be passed. The competitor gaining the highest marks is appointed sergeant of the motor cycle police squad. There are eighteen machines in all doing police work in this city—twelve Harley-Davidsons, five Indians, and one Henderson.

Almost American!

A man recently brought up before the Stratford magistrates was alleged to have no fewer than ten stolen motor cycles in his possession, as well as many accessories. He was an engineer, aged 30.

That Inland Revenue Licence.

We are continually receiving from our readers queries in respect to the Inland Revenue licence, and asking if the querist is liable for its payment. The only circumstances under which exemption from the payment of this tax may be claimed with any chance of success is when the machine is constructed and used solely for the conveyance of goods, *i.e.*, when the motor cycle has a sidecarrier permanently attached.

The Type of Sidecar Body.

The sidecar body must be of the real sidecarrier type, and a touring body used for the carriage of goods does *not* come under this exemption.

Occasional Carriage of Passengers.

We are also frequently asked, "May I use my machine to carry a mechanic to help me in a job? My machine is fitted with a sidecarrier constructed for the conveyance of goods, and I use it chiefly for the carriage of tools. In the event of my needing help on a particular job, may I take a helper in the sidecar?" This is purely a matter for answer by the local authorities. If they are reasonable, nothing will be said; if they are normal, the result will be prosecution and conviction.

Petrol and the Tax.

It should also be remembered that if you have to pay the tax you immediately surrender the right to use free-of-duty petrol, and if you have already obtained a free-of-duty licence when you were fined for taking a passenger in your sidecar you will almost certainly be required to refund the full amount of the petrol tax that you have been excused from paying.

Some Advice.

Consequently, think twice before giving anyone a lift in your sidecarrier.

Queries on Postcards.

We do not make a practice of answering queries sent to us on postcards. Needless to say, our rule *re* the inclusion of the stamped and addressed envelope is broken by these queries, and, moreover, we hardly feel flattered at receiving a mere postcard asking for information that may require some hours' search before it is available.

Some Case!

A motor cyclist was recently dragged up in court to answer no fewer than six charges at once: (1.) Using petrol illegally. (2.) Driving without a proper silencer. (3.) Driving without a licence. (4.) Driving an unregistered motor cycle. (5.) Fraudulently using an index mark. (6.) Allowing the numbers to be obscured.

The defendant was, however, a member of the A.C.U., and was defended by that body, with the result that the whole case was dismissed on payment of the costs.

MILITARY NOTES.

A D.C.M., an Old "Contemptible," and Some Optimists.

D.C.M. FOR A FORMER MEMBER OF THE M.M.G.S.

WE are glad to learn that Sgt. Alfred Black has been awarded the D.C.M. for gallantry in the field. He enlisted through *The Motor Cycle* in the M.M.G.S., and after doing good work with the motor machine guns, and seeing no hope of going to the Front as soon as he wanted to, he transferred to the L.A.M.B. He was sent Overseas to Mesopotamia, where he has been since a year last October.

Sgt. Alfred Black, D.C.M., formerly with the M.M.G.S., now attached to the L.A.M.B. This snapshot was taken in Mesopotamia.

* * *

AN OLD "CONTEMPTIBLE."

TRAVELLING from London to Coventry recently we noticed a young officer wearing the Mons bar. A second glance revealed the fact that the soldier was Roy Lovegrove, well-known prior to the war as an expert Scott rider. Lovegrove went out as a motor cyclist with the first B.E. Force, and, seeming to possess a charmed life, is one of the few original despatch riders still serving. He is now a captain in the A.S.C., M.T.

* * *

WELL-KNOWN MOTOR CYCLISTS IN FRANCE.

WE recently had a brief but interesting letter from Sgt.-Maj. Sidney George, but he unfortunately does not send us his address. He writes from France, and says that he had recently the good fortune to run across Cpls. "Bizzy" and Harry Bashall. Both he and the Bashalls are fit, and all three hope to have a good time together when the war is over. Harry Bashall is driving a "high-speed L.G.O.," while "Bizzy" is running about on a Clyno sidecar combination. Sidney George is in charge of a motor cycle repair shop.

"CUSHY" JOBS AGAIN.

"TANK Driver," replying on the ever green topic "Danger in the A.S.C., M.T.," says:

"As a Tank driver who went through the whole of the third Ypres and Cambrai battles, I would inform Cpl. Richardson, who wrote in January 31st issue, that no M.T. man drove a Tank in those actions, and that if an M.T. man even entered a Tank at all he did so against all orders, and would probably have been detained by the crew, which consists *entirely* of Tank Corps men.

"I may add that I have never seen an M.T. man in any other capacity in a place that our fighting troops would not call 'cushy.'"

* * *

TWO WELL-KNOWN PRE-WAR RIDERS.

WE have received a letter from C. Pearson, who, before the war, was a rider of Douglas and Williamson motor cycles in numerous competitions, and was employed at Messrs. Douglas Brothers' London depôt. He is at present in the R.N.A.S. and engaged in overhauling and tuning aero engines.

He writes: "You may guess I still take an interest in motor cycle matters, and look forward to some big developments in the trade in the near future. I am writing to inform you of the sad news just to hand of Mr. Victor Garland's death. No doubt most of your readers remember him as a very keen motorist, who took part in the early competitions on Chater-Lea motor cycles and sidecar, and also on an 8 h.p. Williamsom sidecar combination. Garland had been serving the country for some time in the motor boat reserve, doing patrol work. I understand he was taken ill and passed away in Edinburgh Hospital on November 24th last. I feel confident that all his past friends will join me in expressing deep sympathy with his relatives through the medium of your valuable paper."

* * *

GALLANT ENGLISHMEN WITH THE FRENCH RED CROSS.

THE British Committee of the French Red Cross have just heard of the further award of decorations on a number of their volunteer motor ambulance drivers serving in one of their convoys in the vicinity of Verdun.

The names of the drivers so honoured are Mr. A. A. Hannay and the Hon. C. Hill-Trevor, Croix de Guerre with silver star; Messrs. J. Bower, W. D. Linsell, and E. Hartley Hacking, Croix de Guerre with bronze star.

* * *

MEDICINE FOR CROAKERS.

SGT. A. CONNELL sends us a brief letter and a photograph of a group of D.R.'s, which, it will be admitted, does one good to behold, for cheerfulness and optimism seem so very evident. He says:

"I am sending a photograph of the Guards' D.R.'s, most of whom have been in fighting up and down the Western Front since Loos, and are proud to have been chosen for this Division. Heartiest wishes to your excellent paper, which is eagerly looked for every week."

A group of the "Guards" D.R.'s, most of whom have been in the fighting up and down the Western Front since Loos. Reading from left to right—Back row (standing): Cpls. Abrahams, Gunn, Nesbitt, Broughton, Callaway, Davis, Reeve, and Ellis. Front row: Cpls. Gyles (on machine), Drew, Gyles (Art.), Cleland, Dudley (on machine), and Sgt. Connell.

LETTERS to the EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

PATTERN FOR PISTON.

Sir,—Being somewhat interested in the art of pattern making, and particularly in the article on the above subject in the issue of January 31st from the pen of "H.H.," may we be permitted to ask your correspondent to explain how the pattern he describes is to be moulded?

Sheerness. WOOD BUTCHERS.

A GOOD EXAMPLE.

Sir,—I thought perhaps that you would like to know that an old reader has responded to your appeal *re* "Join up now."

I feel sure that many motor cyclists after reading the appeal will become members of the A.C.U., as no doubt this is the first time the benefits have been so clearly explained.

HERBERT MORGAN.

ACETYLENE IN DIESEL ENGINES.

Sir,—I have a suggestion to put before you and the readers of *The Motor Cycle*. There have been many suggestions for the use of acetylene in internal combustion engines, but I think that it might be specially adapted for use in the Diesel engine. It seems to me that it would be impossible for a backfire to occur. Of course, as far as my limited knowledge extends, there are no makes of motor cycles or cars on the market which are equipped with Diesel engines, but I quote the old words, "Necessity is the mother of invention," which perhaps means that they may become universal some day. ERIC WADE.

FLYING IN A CURVED PATH.

Sir,—I wish you would grant me the opportunity to point out that your correspondent "Dyne" has inadvertently taken a rather unfair advantage of me, for, as you will no doubt be aware, the letter "Dyne" criticises was posted only four days after "Dyne's" first letter appeared in print. In reply to the assertion that there is one body, *i.e.*, the earth, travelling in a curved path under the impulse of *one* force, I must beg leave to differ; as a matter of fact, this statement controverts many accepted facts of astronomical science.

At the risk of appearing didactic, I should like to point out that there are many hundreds of forces acting on the earth, the most important being (1) the earth's own velocity and (2) the action of the sun, without mentioning such trivialities as the influence of the earth's satellite and the rest of the solar system. Moreover, the assertion that the earth is "still lapping round its curved path with undiminished vigour" is quite unfounded, and is considered by eminent authorities still *sub judice*.

I notice with regret that "Dyne" still adheres to a very loose and easily misconstrued construction of the King's English, but, apart from this, I am content, with "Dyne," to abide by Mr. Aston's solicited "convincing and entertaining" explanation. G.E.H.

Leeds.

Sir,—Under the above title, I have seen several letters lately in *The Motor Cycle*. Some of them reveal a lamentable lack of knowledge of the elementary principles of dynamics.

The definition of a force is "That which changes, or tends to change, the state of rest, or *uniform motion of a body*."

Newton's second law of motion also tells us that force = mass × acceleration.

The cases of the earth's motion round the sun and of a shell travelling in a non-resisting medium are therefore instances of bodies describing curved paths under the influence of a single attractive force. Their initial velocities, as Mr. Ellison says, would carry them on to infinity, if there were no force to change their paths. But a velocity is not a force. The force which caused the velocity has now ceased to act.

The only force acting on a shell in a non-resisting medium is the earth's attraction. This force generates an acceleration vertically downwards, and so an ever increasing velocity in the same direction. The shell has at any moment two velocities, one in the direction of projection and the other vertically downwards. The resultant of those is the path described by the shell.

Mr. Walmsley says, in his letter in your issue of January 10th, "For a given mass and accelerating force, acceleration is proportional to time." He is contradicting himself, for if the force and mass are given then by Newton's second law the acceleration can be determined, and, of course, has a constant value. It cannot, then, be proportional to a variable. What he perhaps means is "For a given mass and a given force the velocity is proportional to the time."

D. A. FAIRWEATHER.

BRITISH MAGNETOS

Sir,—Some time ago I was journeying from Southsea to Birmingham on my 2½ h.p. New Imperial-Jap, and up to then had had no trouble whatever with the machine, and I have covered over 10,000 miles, but when nearing Oxford I experienced misfiring, which I eventually traced to the magneto, and found the gap had by some means almost closed, and, having no magneto spanner with me, I took the very risky course of bending the rocker arm with pliers until I got sufficient gap, and by this means was able to complete my journey. On arrival in Birmingham, I took the machine to the makers of the magneto, namely, the E.I.C., Sampson Road, and asked them to look at the magneto for me and also put it in order. They overhauled it for me, altering it from anti-clockwise to clockwise, put an entirely new contact breaker complete with plated cover and cap, and when I asked for my bill I was astonished to find that there was nothing to pay. Just before the war, I had occasion to return a Bosch magneto to the Bosch people for overhaul. They did exactly the same work, the only difference being that I received a bill for £1 19s. 6d. Comment is needless. Of course, the usual disclaimer. C. E. HENLEY.

THE IDEAL SOLO MOUNT.

Sir,—In reply to "Cadet's" letter in your issue of the 25th ult., I agree with him, as far as the petrol consumption and tyre wear goes, that the lightweight beats the 3½ h.p. single. I have a 3½ h.p. Rover, clutch model, which, I think, cannot be rivalled for speed, power, and hill-climbing. I prefer a 3½ h.p. single to a lightweight for the following reasons: (1.) The heavier machine will hold the road better, and so reduce road vibration. (2.) You can attach a light sidecar without straining the engine. (3.) Greater speed. I can do 55-58 m.p.h.; with a little tuning, 63 m.p.h. can be attained.

I can get 80 m.p.g. on my Rover, and admit the lightweight beats me here. But I think this is counteracted by the above points, as I would rather have greater petrol consumption and less road vibration than *vice versa*. Before owning the Rover I had a 2½ h.p. two-stroke, and also a 3½ h.p. Triumph, so I can claim to have had some experience with a lightweight. The Rover has satisfied me in every way, and, although only a single-speed, it has climbed every hill I have yet met. BIG SINGLE.

Dartmouth.

SPRING FORKS.

Sir,—A few months ago you published a photograph and a description of a Triumph which had been transmogrified by its owner.

He substituted Rudge spring forks for the shock absorber of the Triumph, but ultimately, I believe, reverted to the standard Triumph forks. Why?

Having owned both makes of these machines, I should be much interested to hear why the excellent Rudge fork did not succeed, apparently, on the Triumph. Will the owner enlighten us?

ALLON.

GOODS MADE IN GERMANY!

Sir,—The whole question seems to me to depend on our winning the war.

If there is any patched-up peace the Hun will never get one farthing of my money to encourage him to further aggression; but, on the other hand, if he is thoroughly beaten, I think I have enough knowledge of his character, obtained by residence in his country, to feel that he will, with a little more humility and commonsense, direct his culture into less militaristic channels, and so make reconciliation more possible.

I trust that the "strong" gentleman, who is going to "discuss (!) the matter" with the "little" one in the presence of his armed friend, will not send me his address for saying this. I am a man of peace, at least, whenever possible, but meanwhile let us get on with the war.

W. G. ROBERTS.

Sir,—May I crave a little space in your excellent journal for a few remarks concerning "Goods Made in Germany?" After reading at some length the views of two different schools of thought, I have come to the conclusion that it is a matter entirely for one's own personal opinion and point of view—a matter better to be decided individually rather than collectively. To me it seems both needless and futile for the two rival camps to try and thrust their opinions down one another's throats. Liberty of thought in this country entitles each side to its own views. Unfortunately, the correspondence has not unfrequently degenerated into mere personal and mean insinuation—a thing very much to be regretted. The present-day paper shortage might very well be extended to letters, of that character!

But my object in writing to you, sir, is to suggest that, as the two sides have had a fair and proper hearing, you should now declare the correspondence closed, as no useful purpose is served by allowing the columns of a sporting paper to become an orgy of political controversy.

Personally, my next mount will be a Britisher with British fittings, for the simple reason of its being far superior to any other.

E. KEITT.

Sir,—May I say that my friends and myself are fully in agreement with your anti-German trade notice, and we shall continue to purchase the journal, even though the price be raised to 6d.

R. A. V. WILKINSON.

Sir,—It is quite apparent that Messrs. Ives and "R.O.W." are men possessing queer notions of decorum and propriety.

Apart altogether from the fact that the proprietors of *The Motor Cycle* may entertain well defined conceptions of their own, it is rather interesting to examine the logic paraded by Ives and "R.O.W." for consistency and evidences of mental calibre.

Can those celebrities conscientiously assert that the mere fact of your "leanings" on the aspect of Germany's clandestine and inhuman method of conducting war outweigh the purport and utility of your intrinsically valued paper?

It is amusing, and yet painful, to note the fact that those men adopt the exact means of pressure to enforce their case as do the proprietors of the "Blue 'Un," viz., by boycotting the paper, or, more certainly, by refusing to support it. I mean the same means are being used to attain given ends.

That the proprietors are not moral cowards is evident from the fact that letters "for" and "against" have been duly published.

I have a strong feeling that Ives and "R.O.W." have a sneaking regard for your fine paper, and "behind the door" will search its columns, more especially for help.

In the business world one learns to make debit and credit columns, thereby following attenuated results. In following this practice I shall only discard your paper when it ceases to be a font of pleasure and information. And may the "ethereal blue" prevent the possibility of religious or political bigotry entering within its domains.

To discard a man because of an expression of his, irrespective of the sum total of his other good qualities, is to stoop to low-mindedness and crass bigotry.

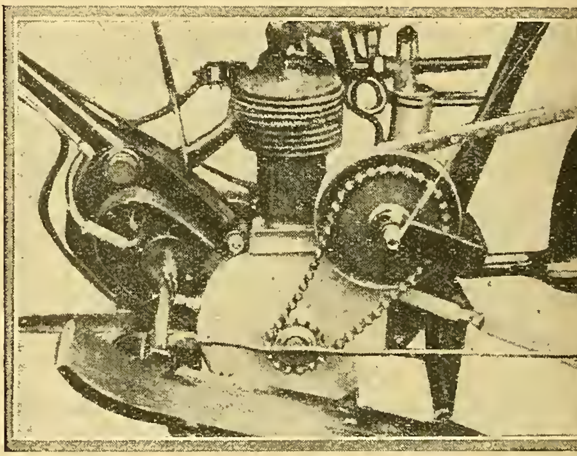
Of the war I have my thoughts and findings. I shall carefully nurture and pursue their sequences unobtrusively. But, in conclusion, may I suggest that my two *confrères* (motor cyclists) proceed to the bath of enlightenment and reform and there wash themselves. The operation will be healthful, and will refit them, with a needful spirit of tolerance, rectitude, and wisdom for re-entrance to the numbers of your valued readers.

D. SHARP.

HOW MANY GEARS?

Sir,—I have followed "Ixion's" writings for a considerable time, and have derived much pleasure and education from them. At the present time I notice he is referring to speed gears.

My opinion, after having used motor cycles, combinations, and motor cars from the earliest types, is that the multiple gear is the gear. It enables one to maintain a more constant engine speed, and does away with the unreasonable engine racing that is often so much indulged in to maintain a reasonable average in m.p.h. This in itself must relieve the engine of much undue wear.



Armstrong hub fitted as a countershaft gear.

Personally, I used to ride a machine fitted with a hub gear in the countershaft. This, I find, is very silent; it is very simple to change gears, and is approximately twice as strong as if fitted in the rear wheel. There is also another feature. Revolving as it does, it acts as an extra flywheel effect, which cannot in any way be otherwise than beneficial.

Enclosed you will find a photograph of a motor cycle to which I fitted one of the very earliest Armstrong cycle gears. It was a very strong model, much better than the later ones. An ordinary free-wheel was fitted on the outside, so that the internals were positive gears. This was fitted on the motor as shown with a chain wheel in place of the free-wheel; two flanges screwed to one spoke ring to form a belt pulley, making a neat three-speed gear. The control was on the top tube, as shown, and the wire conveyed *viâ* the saddle to the gear. It was an excellent addition to the machine, and contributed much to the pleasure of riding. This was in 1913. The machine I disposed of, and I have no idea where it is now.

At the present time my machine is the Syke cycle car, illustrated in *The Motor Cycle* some little while ago. This machine has a T.T. hub gear fitted in a countershaft position, and I must say that the gear gives excellent results. The top gear is approximately $4\frac{7}{8}$ to 1, yet the climbing properties of the machine are remarkable, with a load of two adults and one child.

I am now looking forward to the time when motoring will be permitted, so that I can give some proof of what the car will do. Of course, we must bear in mind the engine capacity is only 614 c.c., yet the machine has gone over Dunmail Raise with two adults and child and luggage, and climbed within a few yards of the top of Kirkstone Pass with the same load.

All being well, on the return of peace I intend to produce these machines, either twins, 5-6 h.p. and 8 h.p., or maybe a four-cylinder air-cooled model—all models to be similar in the chassis construction, only varying in the width of body for single or two-seaters.

JOHN W. TAYLOR.

THE MOTORISTS' PROTECTION ASSOCIATION.

Sir,—I shall be obliged if you can find space in your next issue to clear up the following. Numerous enquiries have reached me from motor cyclists all over the country as to whether they are eligible as members.

This is so. The association is "*out*" to protect their interests equally with those of all private car users on the lines already indicated. I have registered some thirty odd motor cyclists and shall be glad to hear from others as soon as possible. Just on 400 of the 500 members required as a minimum, before the first meeting can be called in London, have now registered their names (this since January 12th); when the number is reached all details will be discussed, and subscription fixed, etc. The latter, I hope, will be merely a nominal one, not exceeding £1 1s., as the association is "*out*" for *business*—not *social functions* and *wayside salutes*.

H. E. SAUNDERSON, Hon. Sec.
"Sussex House," 42, Howard Road, S. Norwood, S.E.25.

A SPORTING CHALLENGE.

Sir,—I am very pleased to see that my challenge to ride my K model Harley against any s.v. 85 × 85½ J.A.P. has been accepted by "A.C.," Cardiff.

With reference to conditions, I am willing to ride solo or sidecar on Brooklands any distance up to 500 miles, weights of both machines to be the same, and all other conditions equal. As I am at present in France, I am afraid it will be impossible to meet "A.C." until after peace is declared. If you will bring this match forward I am sure both "A.C." and I will be greatly obliged.

I shall be glad to consider any suggestions "A.C." may offer to make the match more sporting.

May I suggest to "Triumph" to try something more accurate than even the good speedometer he mentions, when I am sure the speeds claimed will be very different?

I might mention that the hill referred to by Lt. Addenbrooke in your issue of January 24th has been climbed this year by a Ford box car with three up on top.

B.E.F. S. A. MARKS.

ROTARY AND RADIAL ENGINES.

Sir,—I read with interest the article on "Rotary and Radial Engines" in *The Motor Cycle* of February 7th. I admit that the rotary and radial engines have made enormous advances during the last few years, but I think it will be some time before they become satisfactory when fitted to motor cycles. My reasons for this opinion are:

(1.) Even if the engine were successfully fitted in a frame or rear wheel these types require very much more attention than the reliable engines we are used to at present.

(2.) High petrol and oil consumption. In an aeroplane engine about nine to ten gallons of petrol and six to eight pints of oil are consumed in an hour. In the smaller model fitted to a motor cycle this would be greatly reduced, but even then it would be much more than the consumption of a single or twin of the same horse-power.

(3.) The oil-slinging capacity of the rotary type. The public are clamouring for clean machines, *e.g.*, good mudguarding, etc., and an oily machine would not be very popular unless enclosed. In the summer, when riding in dusty districts, it would be an awful job to clean off the congealed dust and oil at the end of a long ride unless the engine was totally enclosed, when it would seize for want of a cooling head wind.

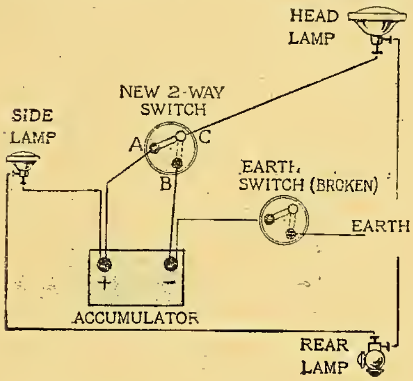
(4.) With the rotary type the engine would certainly have to have some efficient form of shield, because if a piece of the rider's clothing, or any part of him, should touch the engine there would be a nasty accident. If, to get over this, the engine were placed in the back wheel, it would have to be placed on a sort of belt rim to enable a hub gear and clutch to be used, and this would make the wheel lopsided, as well as increasing the tyre wear.

I do not want to give the impression that I think radial or rotary engines will never become popular when fitted to motor cycles, but I think they will have to be greatly improved.

CADET.
Dartmouth.

WIRING AN ACCUMULATOR SET.

Sir,—I am taking the liberty to write to you on the subject of "Chinook's" lighting problem, propounded in *The Motor Cycle* for December 27th. I am sure you will pardon the liberty and the lateness of so doing, but our mails take some time to filter through. I have read the replies in the next issue, and none of them seem to answer "Chinook's" question—*e.g.*, "but I am still hankering after a system whereby, by the addition of another switch and a yard or so of wire, all three lamps can be thrown into series." This can be done by the addition of one two-way switch and a very little wire. The enclosed sketch, I think, reduces alterations to a minimum, which, of course, is what is required.



With the two-way switch making contacts A and C, when the earth switch is made: Head lamp, full brilliancy; side and tail lamps, half brilliancy; break earth switch, no lights. With two-way switch making contacts C and B: Earth switch broken, all three lamps in series; earth switch made, side and tail lights only.

LIEUTENANT, R.N.

FLYING FACTS AND THEORIES.

Sir,—I much appreciated Mr. Aston's reply to myself and "O.J.F.S." on the subject of the "feel" of the machine in your issue of February 7th. I feel, however, that I must venture to differ from him in one respect. He says that I did not describe the "feel" of the machine, but rather that of the pilot. I contend that, except in the case of a "stall," during which the controls go limp, the feel of the pilot *is* the feel of the machine. Take an instance which appeared in my last letter—that of an inward side-slip. This is not necessarily brought about by a "stall," but rather by overbanking. The centrifugal force, as set up by the effect of the rudder, is not sufficient to keep the aeroplane from slipping. There are two ways of finding out what is happening: first, by looking at the "bubble" or spirit level—in my opinion a most unreliable and unnecessary gadget; secondly (which goes to prove my contention), by the sensations experienced by the pilot. The feel of the controls will not tell the pilot that he is side-slipping. There is no outward sign on the part of the aeroplane. No, the pilot, by reason of the draught of air on the side of his face and the "tube lift" feeling, knows that he is slipping, and corrects his error accordingly. I am convinced that the expressions "feel of the machine" and "feel of the pilot" mean one and the same thing.

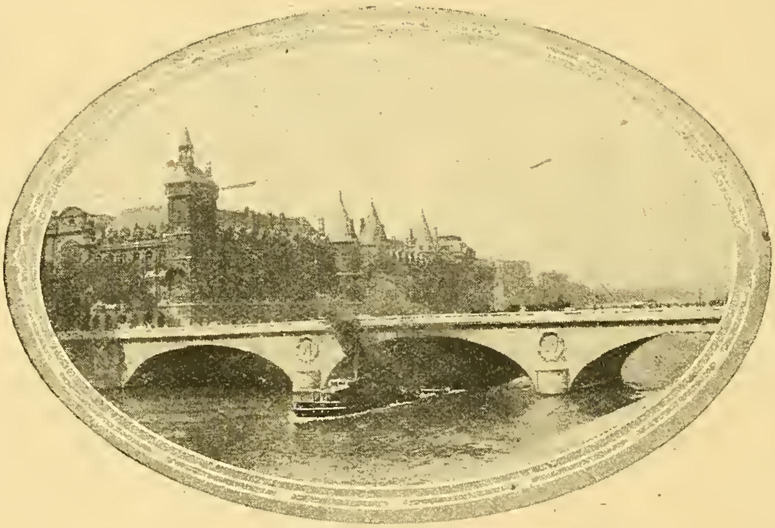
With regard to his problem which appears at the latter end of the article: in my opinion, I should say that the machine which descends in a plain nose-dive would certainly reach the ground before the one which "spun" down. I give a very old geometrical proof in support of this answer: that of "the shortest distance between two points is a straight line." The nose-diving machine carries out this formula. On the other hand, a spinning nose-dive is nothing more than a very exaggerated spiral, and, as such, covers a greater distance in the fall than a nose-dive. I do not know, and shall be interested to hear from Mr. Aston's solution of the problem, whether the spinning motion of the second aeroplane imparts to it an extra momentum which enables it to equal the speed of the first, but, judging from the fact that I have watched a machine performing both these "stunts" before venturing an opinion, I should say that it does not.

JACOBUS, R.F.C.

LITTLE SKETCHES IN PRE-WAR FRANCE.

II.—ROUND ABOUT PARIS.

AFTER breakfast at the "Café de la Grande Marquise," the breakfast being a large oily omelette, *café nature* (that is, denuded of alcohol in one pernicious form or another), a foot or so of honeycomb bread—the whole partaken of hungrily—after breakfast, I say, we walked out on to the Asnières Road, with pipes fuming happily, content to await the day, and knowing that what it held would be good. My friend, with whom I was taking this never-to-be-forgotten holiday, stalked serenely along, clad in a joyous masterpiece that represented some American tailor's nightmare of an English Norfolk jacket—a very Joseph of a coat. For myself, I looked a person to whom it would be correct to give a penny. Yet the polite stares of the amazed inhabitants of this little Paris river resort disturbed us not at all. We were here, at last, in the Promised Land; and what did clothes matter if a man had a few pounds, and enough English tobacco to render distant and negligible the day when one would have to smoke the pungent and terrible Scaferlati? What does anything matter when the demon of work has been exorcised for a few weeks, when one wanders — a gentleman at large —in sunny France.



The Palais de Justice, looking across the Seine.

Down the road, slowly meandering, accompanied by the queer, yearning twittering of his reed pipe, comes the goatherd with his erring flock, bearded dispensers of the morning milk, always on the verge of suicide under the clanging street cars that rattle by at all hours. A humped figure bumps by at hectic speed, a Frenchman with a *pavé*-proof spine on an antique 5-6 h.p. Peugeot, coil and accumulator complete. (We saw very few machines in France, and those mostly lamentably out of date; with the exception of one or two New Hudsons, which had very complete instructions on the tank explaining in French the use of the controls—a sensible idea.)

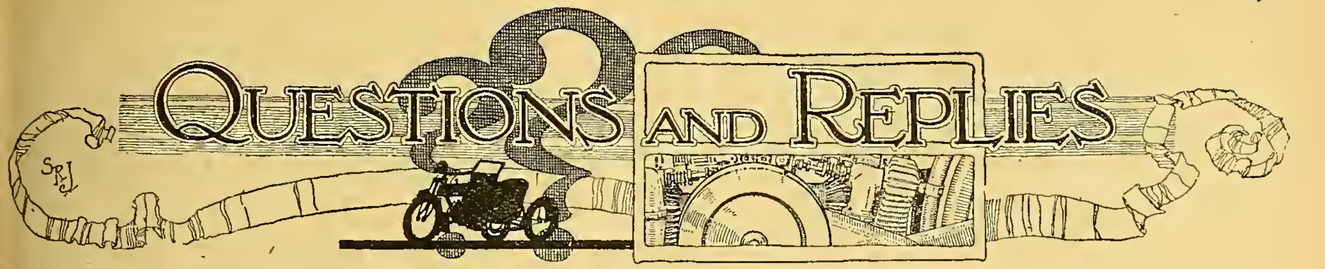
We stood at a street corner and lazily discussed what we should do. Should we horrify the fashionable ones on the boulevards with our pawn-shop get-up; should we laze a day in the Bois (dear Paris park, beloved of the bourgeois, and all the little bourgeoisie); should we stroll appreciatively round the Luxembourg galleries and tire ourselves? Perish that last thought on such a golden day! The river, then. A steam car thundered down the cobbled road: we climbed up to the three sou roof, where one can see and admire. The car jolted through the long squalor of Levallois Perret, past the gate of Asnières and the vigilant *octroi* officials, down tree-shaded avenues hemmed with tall white buildings, light and graceful, to the great church of the Madeleine.

The River Seine.

Here we clambered off, and essayed to cross the road. This is always an adventure. One had need of as many eyes as Argus to save one's skin. Across the desert-wide stretch of the Place de la Concorde, past the little shrivelled old woman who sells leathern cakes (yclept gingerbread) for two sous to adults and one sou to children, down the dip to the golden river, Seine, the river of bridges. Bas Meudon looked attractive on the prow of the steamer. Up the gangplank then, and there we sit, delightfully at ease among the heterogeneous Paris crowd, watching the water swirl away from us, the long green banks, the white buildings clotted together, the Eiffel Tower—"to Paris what a delicate tiara is to the head of a beautiful woman," as its designer said of it. I proposed that we should load up with eatables at whatever shops Bas Meudon might produce, and hie to the woods for the day. The peaceful river scenery glides by, broken now and then by tugs, belching smoke and flame, trailing strings of huge barges loaded with—cigarette papers, of all things. How many billion of the little things could there be on each barge? Why speculate, why not just enjoy? A fat *curé* opposite us blinks in the sun. Wherever one goes in Paris there is always a fat *curé*. Two chattering American girls near us load a kodak with fresh spools. On the bridge the mahogany-coloured pilot gazes sternly into infinity, and twirls his brass-bound spokes with the air of a Columbus.

On Happiness.

Then we bump heavily into a landing stage, placarded on every available square inch with advertisements, of things to eat, drink, sleep on, and what not. "Bas Meudon!" Up a steep hillside runs the funicular railway, half lost to view in the foliage. After securing provender, we are drawn to the top, where inviting green aisles beckon us. There, as happiness is an uneventful thing by the very nature of it (even perhaps a little dull!)—there leave us then, with the rabbits jumping about us, and the blue of the sky glimmering benignly through the tree tops.



A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

A Loose Ball Bearing.

"Ixion" recently wrote that he was busy securing a loose ball-race in the aluminium case of a gear. I have the same trouble with my 4¼ h.p. motor cycle gear box, and would be grateful to hear of a permanent cure.—T.W.

If you pack the ball-race in with a thin strip of brass or even of brown paper, provided it is tightly fixed and the shafts are properly in line, there is no reason why the cure should not be a permanent one.

Piston Rings Breaking.

Can you suggest any reason why my 3½ h.p. single-cylinder 1911 Indian should break its piston rings? If driven hard it is possible to break them both in about thirty miles, but if driven carefully (*i.e.*, not all out for more than five minutes at a time) the rings break every 500 miles or so. They usually break in two places, about half an inch from the slot on either side. The engine behaves well in every other respect, and does not get exceptionally hot.—G.S.A.

The breakage of the piston rings may be caused by the rings being a bad fit or by overheating or partial seizure, due to an insufficiency of lubricating oil. Perhaps when you do drive "all out" you do not take the precaution of giving the engine an extra pumpful of oil.

Petrol for Soldiers on Leave.

I see by your paper that it is now possible to get a temporary permit to use a motor cycle and petrol. As I am expecting to be home on leave shortly, and should like to be able to use my outfit, I should be obliged if you would let me know how I can obtain the above.—S.E.P.

The course for you to adopt is to apply to the Petrol Controller, 19, Berkeley Street, London, W.1, asking for a temporary permit to be issued to you, and stating also the circumstances of the case in detail. It is advisable to begin this application at least three weeks or a month before you are likely to come home on leave, and you should state the date on which you are coming home and the dates between which you want the permit to operate. If you will be coming home in less than three weeks, the best course to adopt is to write the Petrol Controller, and tell him that you will call personally for the permit when you arrive in Town.

Carbide Consumption.

What amount of carbide would be necessary for 200 miles night work on a 2¾ h.p. Douglas in a very bad country, both as regards gradients and road surface? The average speed might be 15 m.p.h., probably often less. My lamp is a Lucas King of the Road—smaller set. The makers say the generator burns about four and a half hours—which I doubt. The 200 miles would not be ridden off at one stretch, but perhaps on seven or eight different nights.—W.H.M.

It is usually estimated that you can get three charges out of a 1 lb. tin of carbide, each charge lasting about four hours. Now, if you average 15 m.p.h. you may reckon that you would require just under one and a half tins. Two tins would be ample, and would make the necessary allowance for waste, as the burning is not to be continuous.

Dismantling an Engine.

Will you be so good as to help me? I am taking down the timing gear of my 1913 8 h.p. J.A.P., but am held up with the exhaust lifter, so will you please tell me: (1.) How to remove the exhaust lifter so as to be able to take off the rockers? (2.) How to clean carbon from the inside of the curved exhaust pipe? (3.) Would you give me the name and address of a repairer of petrol and drain taps, as mine leak badly? Or would you recommend new ones (if so, the name and address of makers would be acceptable)?—H.S.

(1.) We believe that the exhaust valve lifter in your particular model consists of a rack and pinion and a double cam. If you remove the timing gear cover, you should be able to pull away the pinion, together with the double cam and shaft, without difficulty. See the illustration on page 1365 of *The Motor Cycle* of October 23rd, 1913, a copy of which issue will be supplied to you for 7d. post free. (2.) We should recommend you to put the exhaust pipe in a brazing hearth and heat it red-hot. This would burn out a great deal of the oily carbon, or an oxygen flame, similar to that used in the Cylclean process, would clean it satisfactorily. (3.) Probably Messrs. Rotherham and Sons, Coventry, would repair the taps for you.

In submitting to the Editor articles, photographs, or drawings, contributors are asked to mention whether the illustrations are exclusive, and further to enclose a stamped addressed envelope for return of unaccepted contributions.

A Slipping Clutch.

I have a 3½ h.p. Triumph motor bicycle, and the three-speed Sturmey-Archer clutch does not act, although the gears work all right. Would you tell me how to adjust the clutch?—W.H.N.

It looks as if either the clutch plates are worn or the clutch requires to be washed out with paraffin and then thin oil inserted, or adjustment is required. The clutch should be adjusted so that there is about a quarter of an inch longitudinal movement before any definite resistance can be felt on the clutch pedal. The length of the long clutch rod should be adjusted so as to release the clutch with a minimum amount of movement of the pedal. Also make sure that your belt is not slipping.

Removing a Timing Pinion.

(1.) I am taking down a 4 h.p. 1915 Triumph, and find I cannot move either the wheel driving the cam wheels or the bearing on the pulley side of the engine. What method do you advise me to use to remove these? I have soaked both in paraffin for several days. (2.) Why does my screwdriver act as a magnet to screws placed on a magneto? It will lift small screws three inches immediately above the magnets, but they drop when they pass the edge.—M.E.B.

(1.) In the centre of the timing pinion there is a screw with a broad head. Use a large screwdriver, and, after exerting considerable force, you will find that this screw can be withdrawn. It is a cone-headed screw, and after it has been removed you will see a key. This should be knocked inwards, and then the timing pinion can be prised off with a couple of screwdrivers. The crank case is now free to be removed, and, if you desire to remove the ball bearing also, this can be knocked out with a piece of hard wood and a mallet. (2.) This does not mean that your screwdriver is necessarily magnetised. The screws undoubtedly are, since they are always in contact with the magnets of the magneto.

Mysterious Transmission Troubles.

My brother in India has a British twin motor cycle which is giving him considerable trouble. He writes: "(1) Neither the clutch nor the belt seems to me to slip, but something slips between the wheel on which are the clutch and belt and the gears. For some time I could move the gears without declutching, and my kick starter went round without moving the engine, but that eventually cured itself. (2.) In spite of the petrol and air proportions being correct, there being no leaks, and the fitting of a 16 jet, I sometimes only get 40 m.p.g., though at other times I get 60. Why should it vary? (3.) What would be a fair petrol consumption with sidecar?"—F.G.B.

(1,) We should imagine that your brother is mistaken in saying that it is neither the clutch nor the belt. If, however, he has conclusively proved that the trouble is in neither of these, then the fault must lie in the gears themselves, and it is impossible to state definitely what it is without inspection. From the description of the symptoms, however, we should imagine it is most probably a case of worn dogs, or bent striker arms or selector rods. (2 and 3.) As regards consumption, there is probably some mistake in the timing, if there are really no air leaks nor any petrol leak. The symptoms seem to suggest that there is a leakage in the feed system somewhere, which may occasionally become choked up, and consequently the consumption temporarily approaches normal, which should be about 60 m.p.g. with a .03 (or No. 30) jet.

Ball Bearing Trouble.

When last out with my motor cycle I was troubled with a grinding sound coming from the crank case. I could move the engine pulley, when the belt was off, with a considerable amount of play, up and down and sideways. I have taken the engine completely down. The ball race bearings are a tight fit in the recesses of the crank case on each side; there seems to be no play whatever in the bearings on the engine-shaft; and I have had the balls out of the ball races and put them back again after they had been thoroughly cleaned. I asked the advice of a motor mechanic, and he said they wanted packing in the crank case. I may mention the ball race nearest to the engine pulley had been revolving bodily in the recess. What I should like to know is—does the ball race want packing between the outside ring and the crank case, or between the side of the crank case and the side of the ball race? What would you suggest I should pack it with? As I have mentioned above, the ball race just goes into the recess, and is a tight fit at that. I possess most of your works dealing with motor cycling, but very little is mentioned about ball bearings.—A.J.W.

If you can move the engine-shaft up and down it is a sure indication that the bearings are worn. Certainly if the ball bearings have been revolving in the crank case they should be packed so that they cannot move. We should strongly recommend you to submit the engine to an expert, as it looks to us as if one of the ball bearings will have to be renewed. The packing should be round the outside of the ball race, so that it cannot turn in the crank case.

Mysterious Loss of Power.

My 5-6 h.p. Rudge-Multi sidecar, which used to be a splendid puller, now konks out on the slightest provocation. It has climbed Llanberis Pass, starting from Llanberis village, with heavy passenger and luggage without a knock, but now it would not do it solo. I have had it retimed—both valves and magneto—exactly to makers' specification, three times. This has been done with minute care, and is, I think, right. The engine is perfectly clean inside and out. The compression is not quite so good as it was. I can stand on the pedal, when it is horizontally placed, about twenty seconds, and it will drop a little. I have tried several size jets with no better results. There is no misfiring, and the engine starts readily enough. Exhaust pipe and silencer are quite clean. Change of plug makes no difference. No parts have been renewed, and there appears to be no tightness in the bearings. Only Prices' best air-cooled single-cylinder oil is used. The controls work smoothly, and engine will race madly "in free."—A Four Years' Reader.

It is exceedingly difficult to advance any helpful suggestions without seeing the engine. Have you tested the cylinder and the piston and made sure that excessive warp does not exist; also, have you tested the compression when the engine is hot? It might be that, when hot and expanded, compression is lost in some way, such as by a slight crack round one of the valve seatings or in some obscured portion of the cylinder. You might borrow, if possible, another magneto and try the engine with this fitted, and the same applies with regard to the carburetter. It is only by the process of elimination that defects of this kind can be located. We take it that you have carefully checked the valve tappet adjustment, valve lift, etc.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY

During 1918 the restriction on the import o' paper and paper making material is very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week.

Misrepresenting a Second-hand Machine.

A few months ago I bought a second-hand motor cycle. The agent from whom I bought it told me at the time of the transaction that it was a Calcott fitted with a 1914 J.A.P. engine. About a week ago I wrote the Calcott firm, and in their reply they told me that they had discontinued to make motor cycles a long time ago, also that they never fitted any J.A.P. engines—they have all been Calcott engines—and, being a novice, I consider I have been treated very unfairly. I paid half the money down and am paying the remainder in six monthly instalments And I think I am paying a very good price for the machine the agent was supposed to have sold me, provided there had been no falsehoods. I should be much obliged if you could answer me the following questions: (1.) Can I compel the agent to take the machine back, provided I take another one of the same value in exchange? (2.) Would it be wise to withhold any of the instalments, provided the agent will not allow me anything back on the motor cycle?—T.R.

(1.) We are afraid you can do nothing unless you have the incorrect description of the machine in writing, or have some other means by which you could conclusively prove the agent to have made this misrepresentation. If you feel that you could prove it in court to the satisfaction of a judge, you may then compel the agent to take the machine back without any stipulation as to your taking another one of the same value in exchange, and, of course, he would have to refund the money you have paid. (2.) You certainly would have no justification for withholding the instalments, as you suggest.

READER'S REPLY.

A Leaky Petrol Tank.

When you want to repair a petrol tank, fill it three or more times with water to overflowing, which will expel all the petrol gas, and you can then solder with perfect safety. Dry afterwards, of course. In case anyone doubts this, the fact that I am able to write will prove that I have not been exterminated while repairing tanks, of which I have done several.—Edgar Evans.

RECOMMENDED ROUTES.

Plumstead to Forest Row.—E.K.

Make your way from Plumstead to Woolwich Common, Eltham, Mottingham, Bromley, West Wickham, Shirley, Croydon, Purley, continue through Godstone, Blindley Heath, and East Grinstead to Forest Row. Approximately 53 miles.

Sunderland to Scawfell and the Lakes.—J.R.L.

Sunderland, Gateshead, Newcastle, Bladon, Hexham, Alston, Penrith, along the shores of Ullswater, over the Kirkstone Pass (which should be negotiable by all modern machines), to Ambleside. Scawfell lies practically due west of Ambleside.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted. Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller. but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged; when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

MOTOR CYCLES FOR SALE.

Humber.

HUMBER, 3½h.p., single speed, £11/10; 3½h.p., 2 speeds, £19/10.—Motor Exchange, Horton St., Halifax. [3447

1915 Humber. 3½-4h.p., mag., 3 speeds, clutch, kick, lamps, nearly new; sacrifice 38 gns.; part exchange lightweight.—1, Ebner St., Wandsworth. [3490

Indian.

INDIAN 1915, 5h.p., 3 speeds, fully equipped, equals new, run 500 miles only; £50.—Below.

INDIAN 1914 7-9h.p. 2-speed Combination, electric equipment, in real nice condition throughout; £36.—Percy and Co., 337, Euston Rd., London. [3338

INDIAN, 5-6h.p., with coachbuilt sidecar; trial; £20, no offers.—Ellard, 437, West Green Rd., Tottenham, N.15. [3518

RED Indian, 1915, 3-speed, clutch, kick starter, good tyres, accessories, just overhauled by Godfreys, splendid condition; best offer.—Wilson, The Gun, Bramcote, Notts. [3421

James.

1917 2-stroke James, complete with lamps, horn, etc.; £37.—Cross, Jeweller, Rotherham. [X1898

JAMES, 1914, 4¼h.p., single-cyl., 2-speed countershaft, clutch, chain drive, T.T. bars; £25 for quick sale.—Box 1,696, c/o *The Motor Cycle.* [X1833

1915 James, 2¼h.p., 2-stroke, 2 speeds, accessories, etc., little used, splendid condition; solid value, £33.—Full particulars, Northwood, Cleobury Mortimer, Shropshire [X1746

JAMES 4¼h.p. 1917 Combination, absolutely new, bought 3 weeks ago; cost over £100; ridden only 36 miles, the property of an officer going to sea; price for immediate sale £87, no offers.—Glenartney, Lee-on-Solent. [X1944

JAMES, all models, new and second-hand; extended payments or exchange; specially built 5-6h.p. combination, dynamo lighting, finest combination ever turned out, £120.—Service Co., 292, High Holborn, London, W.C.1. [X1917

Levis

LEVIS, 2½h.p., late 1916, in perfect condition; £27. —Bruce Wood, Horn Park Farm, Lee, S.E.12. [3435

2h.p. 2-stroke Popular Levis, in good sound mechanical condition, tyres also perfect; £20; opportunity. —Wauchope's, 9, Shoe Lane, London. [3495

LEVIS, 2½h.p., 1916 model E, 2-speed, all-chain drive, T.T. bars, mechanical horn, head lamp, generator, rear lamp, Avon studded tyres, machine as new, unscratched, all tools; bargain, £33/10.—Mebes and Mebes, 156, Gt. Portland St., W.1. [3477

Matchless.

1913 Matchless O.B. Combination, 6-8h.p., excellent condition; £28; no dealers.—Box L5,596, c/o *The Motor Cycle.* [3473

MATCHLESS Latest War Model Combination, complete with detachable wheels, spare wheel and tyre; £120.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter. [3523

7h.p. Matchless Sidecar Outfit, complete with all accessories, M.A.O. engine; offers wanted; inspection at any time.—Grose, Ltd., Marefair, Northampton. [X1641

MATCHLESS 8h.p. Combination, new, fitted with J.A.P. or M.A.G. engines; extended payments or exchanges.—Service Co., 292, High Holborn, London, W.C.1. [X1918

MATCHLESS Combination, War Model, new last August, with lamps, horn, and speedometer, run 1,500 miles, in excellent condition; £105.—J. Sims, Longfields, Kent. [3432

7-9h.p. Matchless, M.A.G. engine, 3-speed countershaft gear, clutch, and kick start, semi T.T. bars, sporting type of coachbuilt sidecar attached, machine is suitable for solo or sidecar use; £75, includes accessories.—Seen at Wauchope's, 9, Shoe Lane, London. [3501

Monopole.

MONOPOLE, 1916, 2½h.p., 2-speed, free engine, hand clutch, Albion gear, lamps, separate generators, footboards, E.I.C. mag., Bates tyres nearly new, chain-cum-belt, very light torpedo (cane) sidecar, 3-point attachment, new rim, nearly new tyre (Bates), perfect order, spare cover, tubes, and belt, tools; exchange higher power combination; what offers?—C. Moseley, Dixon Ground, Coniston. [X1483

Moto-Reve.

2¼h.p. Moto-Reve, variable pulley, good condition, new belt and tyre, engine perfect, spares; £10, or nearest.—Dakeyne, Cheadle, Staffs. [3467

New Hudson.

NEW Hudson, 1916, 2¼h.p., 2-stroke, 2-speed, electric lamps; £27.—Drummond, 16, Jesmond Rd., Newcastle-on-Tyne. [X1875

1915 New Hudson, 2¼h.p., 2-stroke, just overhauled, nearly new back tyre, new Dunlop belt, lamps, horn, etc.; £20.—Chapman, School House, Shottenden, Chilham, Kent. [X1945

New Imperial.

CROW Bros., Guildford.—New Imperial, latest 2½h.p., 3½h.p., 6h.p. models in stock · also sound second-hands. [1047

MOTOR CYCLES FOR SALE.

New Imperial.

IMPERIAL-J.A.P., 2-speed, clutch model, £32/10; all new models in stock; E.P. or exchange.—Service Co., 292, High Holborn, W.C.1. [X1920

NEW Imperial-Jap, 8h.p., 3-speed War Model combination; 109 gns.; delivery from stock.—Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter. [3521

NEW Imperial Motor Cycles, 2 speeds, clutch and kick starter, and lady's models in stock for immediate delivery; trade supplied; no permits required. —P. J. Evans, 91, John Bright St., Birmingham. [X0655

Norton.

NORTON Big 4, all-chain drive Military Model; £82. —Exeter Motor Cycle Co., Ltd., Bath Rd., Exeter. [3524

1916 T.T. Norton, speedy, in condition like new; 55 gns.—Seen at Wouchope's, 9, Shoe Lane, London. [3502

NORTON.—Big 4 Military Model, all-chain, new; also chain-cum-belt; £57/10; E.P. or exchange.—Service Co., 292, High Holborn, W.C.1. [X1925

N.S.U.

HAVING Acquired the entire stock-in-trade of the N.S.U. Motor Co., Ltd., we can supply spares for practically all types of N.S.U. motor cycles. In ordering it is important to submit old parts as patterns.—Eagles and Co., Acton Hill Works, Acton, W.3. [X1891

N.U.T.

LATEST Model N.U.T., 3½-4h.p., free engine, 3 speeds, kick start, J.A.P. engine, like new; £40, complete.—Miller, 62, Hampstead Rd., N.W. [3147

P. and M.

P. and M., 3½h.p., 2 speeds and sidecar, underslung chassis; £22/10.—Motor Exchange, Horton St., Halifax. [3448

Premier.

PREMIER, 1914, 3½h.p., 3-speed, clutch, and K.S., Stewart speedometer, lamp, and horn, £34/15; 1916 combination, £61/15; E.P. or exchange.—The Service Co., 292, High Holborn, W.C.1. [X1913

Radco.

RADCO, 1915, 2-speed, 2-stroke, 2¼h.p., good appearance; £21/10.—Motor Exchange, Horton St., Halifax. [3449

Rex.

REX 1911 6h.p. Twin, mechanical overhead inlet valves, Bosch mag., Druids, splendid order throughout; £18.—49, Renmuir St., Tooting. [X1832

MOTOR CYCLES FOR SALE.

Rover.

ROVER.—All new models supplied; E.P. or exchange. —Service Co., 292, High Holborn, London. [X1919

3½h.p. Rover, countershaft model, fitted with a genuine Rover coachbuilt sidecar, 3 speeds; the combination 55 gns.—Seen at Wauchope's, 9, Shoe Lane, London. [3503

ROVER, 3½h.p., new March, 1914, 3-speed, lamps, tools, and wicker sidecar, all in good running order, been little used; £28.—S. Taylor, Low Haining, Houghton-le-Spring, Fence Houses. [X1885

CASS'S Motor Mart, Ltd., have for sale a Rover, 1917, 3-speed countershaft, 3½h.p., Lucas lamp set, speedometer, mechanical horn, new condition; £57/10.—5, Warren St., Euston Rd., W.1. Museum 623. [3419

ROVER Motor Cycles, 3½h.p. and 5-6h.p. models, in stock for immediate delivery, both solo and sidecar outfits; trade supplied; no permits required.—P. J. Evans, 91, John Bright St., Birmingham. [X0653

1917 Rover, T.T., Philipson; this machine is indistinguishable from new—in fact, it is in better condition than a new machine, only done 500 miles; price 50 gns.—Julian, 84, Broad St, Reading. Biggest light car and motor cycle dealer in the South. 'Phone: 1024. Closed Wednesdays 1 o'clock. [0737

Royal Ruby.

ROYAL Ruby.—All new models supplied; E.P. or exchange.—Service Co., 292, High Holborn, W.C.1. [X1926

Rudge.

1917 Rudge Multi, 3½h.p., free engine, kick start, semi T.T. bars includes tools and accessories, and like new; £55.—Seen at Wauchope's, 9, Shoe Lane, London. [3496

Scott.

SCOTT, 1913, Bosch mag.; £37/10; 2-speed, clutch, and kick starter; E.P. or exchange.—Service Co., 292, High Holborn, W.C.1. [X1921

Sun.

SUN-VILLIERS, 2½h.p., 2-speed coupntershaft, new, £37/16; V.T.S., single speed, new, £30/10; 1916 2½h.p., 2-speed, £28/10; E.P. or exchange.—Service Co., 292, High Holborn, London. [X1937

Sunbeam.

SUNBEAM, 3½h.p., late 1915, with Grosvenor sidecar, all fittings, perfect condition, nearly new tyres, Dunlops, spares, tools; £60.—Woolfenden, 153, Bury New Rd., Heywood. [3483

SUNBEAM Combination, 1916, 8h.p., Lucas dynamo lighting set, electric horn, speedometer, wind screen, perfect condition, little used; £120; reasonable offer considered.—Long, Thornhill, Wardle Rd., Sale, Cheshire. [3250

1917 3½h.p. Sunbeam, fitted with Sunbeam coachbuilt sidecar, 3-speed countershaft gear, kick starter, h.b.c. clutch, fitted with all the best Lucas accessories, including speedometer and tools, beautifully finished, and luxuriously upholstered; the combination complete, which is in condition like new, £97/10.—Seen at Wauchope's, 9, Shoe Lane, London. [3497

Swift.

SWIFT and C.B. Sidecar, 1915-16, 3½h.p., clutch, and K.S., complete with lamp and horn, splendid condition; £49/10; E.P. or exchange.—Service Co., 292, High Holborn, London, W.C.1. [X1923

Trump.

TRUMP-J.A.P., 3½-4h.p., footboards; £19; E.P. or exchange.—The Service Co., 292, High Holborn, W.C.1. [X1915

Triumph.

TRIUMPH Motor Cycles.—For bargains call at Wauchope's, 9, Shoe Lane, London. [3498

TRIUMPH, 1912, 2-speed, excellent condition; £25. —Box 1,669, c/o *The Motor Cycle.* [X1809

TRIUMPH, 1909-10, 2-speed, and free engine, in good running order; £16/10.—Box 1,689, c/o *The Motor Cycle.* [X1830

1916 2¼h.p. Junior Triumph, with all accessories, lamps, horn, tools, etc., nearly new; £46.—Robinson's Garage, Green St., Cambridge. [3335

TRIUMPH, 3½h.p., £17/10; 1912-3, Bosch mag., S.A. free-wheel clutch, £26/10; E.P. or exchange. —The Service Co., 292, High Holborn, W.C.1. [X1914

TRIUMPH, 1913-14, 3-speed S.A., F.E., No. 10 Montgomery C.B. sidecar, unused since thoroughly overhauled at works.—Oakford, 12, Starley Rd., Coventry. [X1675

1912-13 Triumph, with wicker sidecar, new back tyre and tube, valves and belt, Grado gear, Lucas lighting set, Klaxon horn, mirror, and back-rest, guaranteed throughout; £27, carriage paid.—4, Gaywood Rd., Walthamstow. [3489

RIDER TROWARD and Co., 31, 40b, 78, High St., Hampstead.—1914 Triumph, 4h.p., 3-speed, underslung coach sidecar, 42 gns.; solo, 36 gns.; 1913 3-speed Triumph, 31 gns.; 1913 2-speed Triumph combination, 29 gns.; 1914 T.T. Triumph, red finish, clutch model, 31 gns.; 1914 T.T. Triumph, Philipson, clutch, 33 gns.; 1913 T.T. Triumph, bargain, 23 gns.; 1911 standard Triumph, 15 gns.; Triumph spares in stock, from 1907 up, including 1914 4h.p. engine. (D) [3390

The Rules of the Road and of the Footpath.

IN this country, unlike most others, wheeled traffic keeps, or is supposed to, to the left. The rule, of course, has to be observed in towns, but in the country motorists will have noticed that among horse drivers especially the rule is more honoured in the breach than in the observance. This fact has so deeply impressed itself on the minds of some persons, that it has been suggested that there must be some definite reason for this persistent desire to keep to the right, and that as it appears to be more natural to do so the rule of the road in this country should be altered and brought in to line with America and the principal countries in Europe.

Those who have motored abroad, however, may remember that in the open country in France it is just as usual to see a carter driving on his wrong side of the road as in England.

It is a curious fact that a driver cannot be prosecuted merely for disobeying the rule of the road, but, naturally, if while transgressing he should cause an accident it would go hard with him. Now, while we drive to the left in this country, we are supposed to keep to the right when walking. The rule of the footpath is a very free and easy sort of affair; few people are aware of its existence, and those who are generally forget it. One has only to watch the throng of people on a crowded pavement to note that no rule at all is observed—some keep to the right, some to the left, but most to the side nearest the shop windows. No one enforces the rule of the footpath, not one cares how often it is broken, nor if a person through keeping on his wrong side stumbles into another man and knocks him down. In such a case one cannot imagine a magistrate asking the offender whether he had kept to the right or not.

A pedestrian is not bound to walk on the pavement or footpath, but is quite at liberty to walk on the road should he choose to do so, and if he is on the highway wheeled traffic must avoid him. It will be seen, therefore, that the pedestrian is a privileged person, as he is at liberty to roam at will on the road, while if an unfortunate motor cyclist rides for a few yards on the empty pathway to avoid a section of unrolled metal he is liable to prosecution.

It would obviously be fairer to make it law that pedestrians should only walk on the road at their own risk, except when actually crossing or about to cross it, or in cases where there is no footpath. Theoretically it is quite wrong that foot passengers should keep to the right, since those walking on their own side and close to the edge of the pavement are progressing next to and in the same direction as the wheeled traffic in the road, consequently a pedestrian may, and often does, step off the pavement unconsciously without taking thought of what may be behind him. There are strong rumours of newspaper campaigns and other steps to ensure the alteration of the present rule, all of which are steps in the right direction, and the change would be eminently desirable but for one thing, and that is the lawless pedestrian would not bestir himself to observe it.

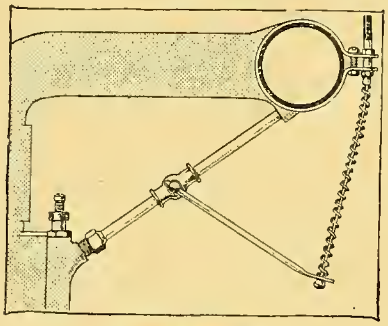
If, however, there were a prospect of the rule of the footpath being enforced the change would be undoubtedly beneficial, as people would be forced to glance at the traffic meeting them before making a crossing, so that they would run less risk and also make the lot of the driver of wheeled traffic a little easier. It simply means that the rule of the road and the rule of the footpath should be the same. In other words, one of them should be altered. Personally, we should say that it would be more desirable to alter the rule of the road, and so bring this country in line with the other nations; it would cost nothing, people would get used to the new rule very quickly, and it would certainly be no appreciable hardship to motorists, a very large proportion of whom, as soldiers, have become used to keeping to the right in France.

An index to the advertisements in this issue will be found on the page facing the back cover

IDEAS: Useful and Ingenious.

AN INDIAN IMPROVEMENT.

THE rough sketch shows an improvement that I have fitted to my Indian motor cycle, which is fairly simple to arrange. An ordinary small tap is soldered on to the pilot jet tube, and a piece of brass tubing sweated on to the handle of the tap to lengthen it. The end of the brass tube is flattened out and bent slightly, and a hole drilled just large enough to pass the end of the Bowden cable through, and this afterwards has a blob of solder on the end.



A petrol economiser.

A clip round the induction pipe provides means of adjustment, while a light spring returns the lever to its original position after it has been operated.

I find this effects a great saving in petrol, as most of the Indian pilot jets are inclined to be rather too large.

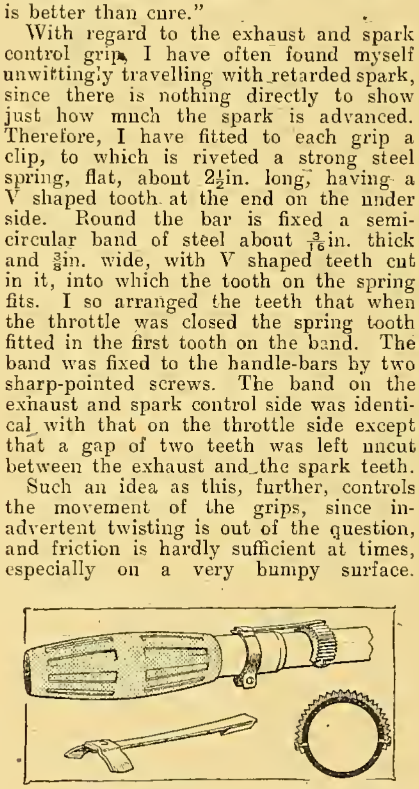
The ordinary single-lever Bowden handle-bar control is used to operate this pilot jet cut-off.—JOHN POTTER, Perth, Western Australia.

TWIST GRIP CONTROL INDICATOR.

ON reading Mr. L. Merlin's letter published in *The Motor Cycle* for February 14th I was tempted to forward the following idea which I have incorporated with the twist grip controls on my Harley-Davidson. I have no fault to find with the twist grip controls; on the contrary, my experience of them has shown me that they are excellent; but, unlike the lever type of control, one is unable to see by a glance when travelling just how much the throttle is open or the spark advanced. The chief difficulty I have experienced is starting up without causing my engine to roar, and it was to remedy this that I incorporated the following idea. I found there was a tendency to twist the carburetter control grip during the leg action of starting up, so that the engine sprang into life with a roar. This is no great detriment, but, unfortunately, my riding is mostly at night time, and in these times of air raids the unexpected roar of an engine in a silent street causes a great deal of commotion, not too pleasant to me, when peoples' nerves are "touchy." The sudden roar has also in the daylight a bad effect upon restless horses. I have caused two "runaways" by this means, happily without accident; but I have come to the conclusion that "Prevention is better than cure."

With regard to the exhaust and spark control grip, I have often found myself unwittingly travelling with retarded spark, since there is nothing directly to show just how much the spark is advanced. Therefore, I have fitted to each grip a clip, to which is riveted a strong steel spring, flat, about 2½in. long, having a V shaped tooth at the end on the under side. Round the bar is fixed a semi-circular band of steel about $\frac{3}{16}$in. thick and ⅜in. wide, with V shaped teeth cut in it, into which the tooth on the spring fits. I so arranged the teeth that when the throttle was closed the spring tooth fitted in the first tooth on the band. The band was fixed to the handle-bars by two sharp-pointed screws. The band on the exhaust and spark control side was identical with that on the throttle side except that a gap of two teeth was left uncut between the exhaust and the spark teeth.

Such an idea as this, further, controls the movement of the grips, since inadvertent twisting is out of the question, and friction is hardly sufficient at times, especially on a very bumpy surface.



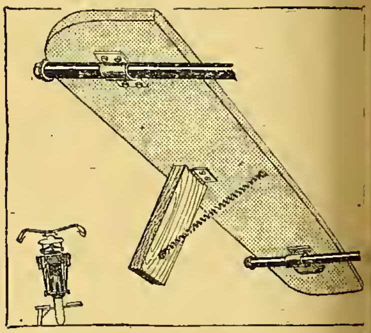
A useful refinement for twist grip control.

Individual bumps have no effect, but a series of bumps, my own experience tells me, causes movement of the grips. To some people this idea may appear needless and unnecessary; but I have found it very useful in traffic, and especially for changing gears silently without loss of power or stopping the engine. On a long trip, although the hands may be taken from the grips without fear of their moving, this idea incorporated makes any untoward movement absolutely impossible, and the grips may be themselves quite loose, but kept in position by the tooth on the steel spring.—H. W. TURL.

A PILOT STAND.

WHEN a motor cycle is used f short runs it becomes very tedio to jack it up on the stand aft each stop, especially since modern mediu and lightweights have reached and su passed the 2 cwt. mark. The followi description, therefore, of a subsidia stand that I recently fitted to 3 h.p. Enfield may be of interest readers.

The materials for this fitment consist a piece or hard boxwood, 6in. long by 2i thick by 1in. wide, a medium streng coil spring, a common door hinge, and few screws. One of the footboards, pr ferably the left-hand one, should be r moved from its carriers and an inclin groove 2.1in. × 1.1in. × .25in. deep cut the bottom of the board at the positi marked X. The hinge is then screw on to one end of the piece of wood a the whole fitted to the footboard in su a position that when open this leg will inclined outwards at a slightly obtuse ang and *not* at right angles. This is essent to the success of the fitment, as it pr vents any tendency for the weight of t machine to close the hinge. The c spring, connected up as shown in t sketch, completes the work, and the fo board may be replaced in position.

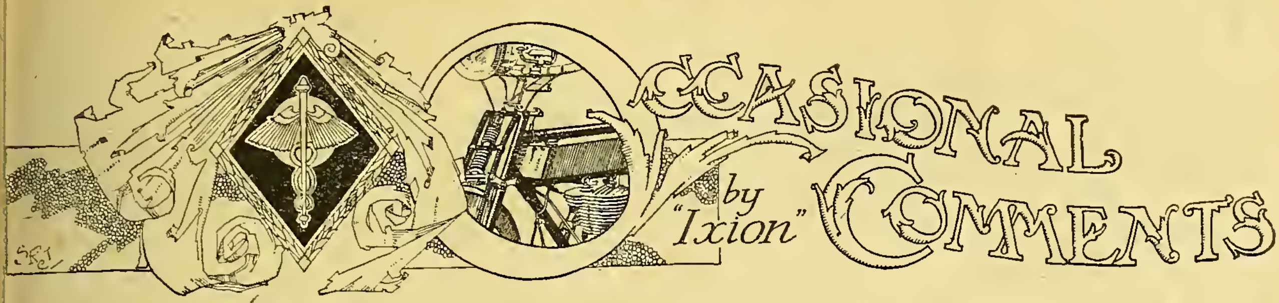


A Pilot stand, a time saving idea

This attachment was found to wo admirably, a slight kick being sufficie to knock it in or out of action, while wh it was in the open position it was fou practically impossible to overbalance t machine. In fact after fitting it t original stand was scarcely ever used.

In conclusion, it may be remarked th the application of this "tip" is not co fined solely to Enfields, for any machi fitted with wooden footboards may easily altered. ARMA

Readers of "The Motor Cycle" a invited to contribute to this page a ideas successfully adapted to their mo cycles. Contributions will be paid fo our usual rates. Rough sketches suffice.



OCCASIONAL COMMENTS

by "Ixion"

New Engines.

MR. PHILBROW owes me a gallon of No. 1, *vide* his letter in our issue of January 31st. So far from being one of his official engine disqualifiers, I am only a humble machine gunner, and had never even heard of him or his engine until he forwarded his complaint to us. I reiterate that his first letter was rubbish. The Government has financed two young engineers who are personal friends of my own, men without cash, influence, or reputation behind them: and they owe their success simply and solely to the merit of their designs—designs which have been approved in sterner tests than the M.M. can impose, seeing that they engage daily in aerial battles with the Hun. That Mr. Philbrow's engine was turned down by the same boards (presumably) does not necessarily prove that his engine is *na poo;* and, being absolutely ignorant of his engine, I was careful to say that he may conceivably have received less than his deserts. I merely refuted his absurd contention that the ideas of obscure inventors do not receive honest consideration and, if necessary, generous financial support. It is, therefore, the facts which prove Mr. Philbrow to be wrong, not I.

Petrol for Some.

I HAVE received various criticisms on my suggestion that grumbles about petrol permits were mainly based on apparent inconsistencies governing the issue. Two points are worth mention. One is that the issue of a universal pass is perhaps a blunder, and causes most of the indignation. A man receives a large grant of petrol on perfectly rational grounds, and, to save ceaseless official supervision, he is given a pass authorising every journey he makes by car or cycle within a given area. Human nature being what it is, he uses his motor for trumpery little trips of no national importance; another owner, who is debarred petrol for any purpose whatsoever, happens to know of this lazy self-indulgence on the part of a more fortunate neighbour, and is not unnaturally annoyed. For example, if you cannot get petrol to go and see your wife thirty miles away at week-ends, you become irate if a neighbour with a universal pass burbles home to lunch daily on a car rather than walk 800 yards. The second point is that personages of real importance must have all the petrol which can be spared for them. Here is a little exercise on the point. Take an A.B.C. railway guide and an engineering trade directory of London or the Midlands. Map out an imaginary day's calls in either of these districts for a man who is supplying steels to a number of firms or superintending the manufacture of ammunition in half a dozen different factories. Normal transport is so reduced and retarded that a full day's work of such a character is literally impossible without the aid of petrol. We cannot afford to keep our brainiest men sitting in trains or hanging round stations half their time: nor can we afford to hang up a gun, or an engine, or a plane for even half a day whilst the man who counts in its production is struggling across country to put some detail right.

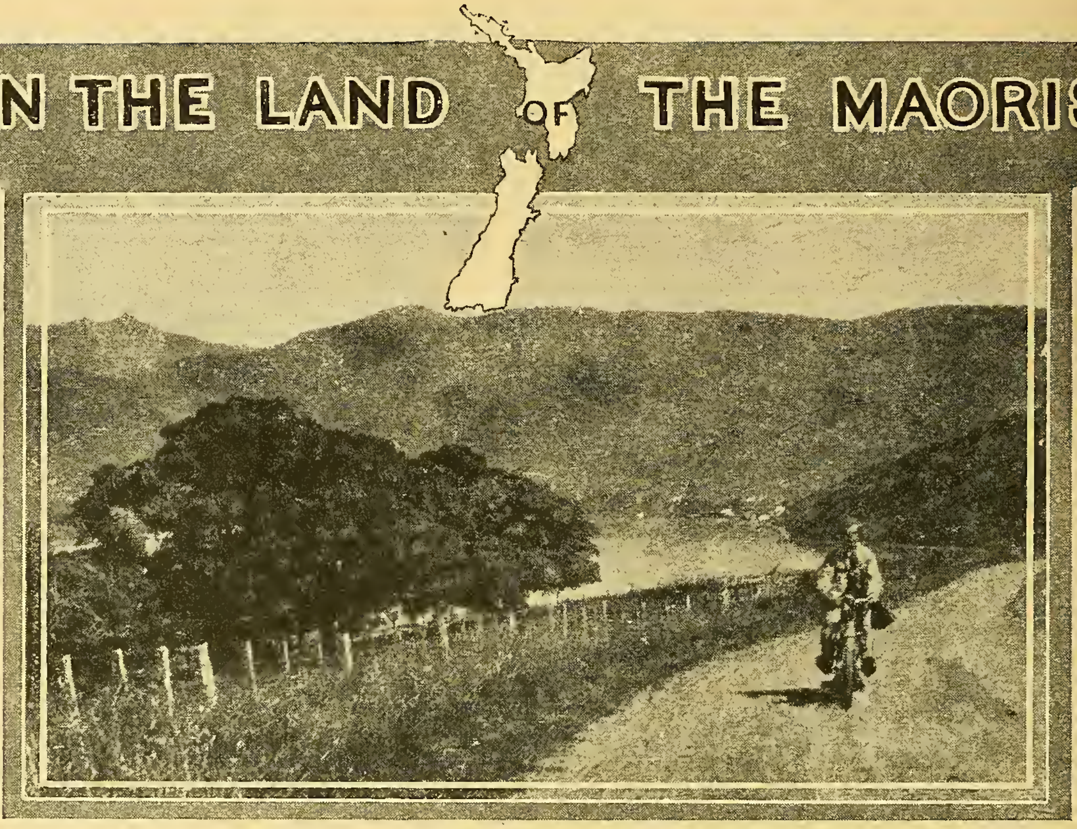
American Machines.

THE truth about American machines is rather difficult to ascertain. I have never been a big twin enthusiast, partly because I eschew sidecars, and partly because my mechanical conscience informs me that I can get the same speeds out of a crack $3\frac{1}{2}$ h.p. if I keep it properly tuned. But a few years ago various people whom I respected thoroughly rubbed the merits of the American into me, and at last I fell from grace and purchased a sample. I encountered immediate and interminable trouble. The twiddly bits strewed the road. The wheel bearings dissolved. The carburetter needle wore like a soft pencil, and after three months, or rather less, the London concessionnaire returned my cheque, and indignantly vowed that he would secure a gold medal in the Six Days with my discarded 'bus, though when it came to the point he did not even enter it. I swore off Americans for some time, until a leading rider and I fell to discussing the extreme discomfort of the average British machine of that date, with its rigid frame, harsh drive, and thumpy, one-lung engine. We agreed to try a pair of imported V twins. He got his first, and a month later paid a special call to release me from my share of the bargain; he stated that his 'bus ran like a dream, but that he was inventing a magnetic broom, which should trail behind his rear wheel and salve the small pieces which fell off.

Some Deductions.

ON the whole, I conclude that American manufacturers have quite recently begun to overhaul British makers in respect of *workmanship*, and that the time has arrived when one may try out one's peculiar ideals in respect of design with no fear of being appalled by badness of material or clumsiness of the construction. I have not hesitated to confess that the single-cylinder with a rigid transmission holds few charms for me, and when imports reopen I am going to buy a big 7-9 h.p. American and see how it suits me as compared with our flat twins. I believe the widespread prejudice against American 'buses is the penalty due to the soft stuff and crude detail work that disfigured the earlier exports, and that this prejudice is now wholly unjust. In other words, if you like a big V twin with a lot of frills on it you cannot beat American stuff, and it takes our own makers all they can do to equal it.

IN THE LAND OF THE MAORIS



At the western end of the Akaroa Harbour, Duvauchelles Road, N.Z.

As the crow flies the distance to the historic town of Akaroa is approximately twenty miles from the city of Christchurch, the capital of Canterbury, New Zealand. To get to it directly by road, however, the prospective tourist must cover fifty-two miles before the pretty little spot, nestling at the foot of the wooded heights of Mount Brazenose, is reached.

It is an ideal holiday resort, and as such is frequented by many business men at week ends and at annual vacations. Accommodation in pre-war days was excellent, and at the best hotels the tariff of 35s. per week could not be considered at all excessive.

The town itself has many of its streets and shops bearing French names, owing to a French colony settling here about the year 1850. The English, however, had forestalled them a few hours by planting the Union Jack on an eminence overlooking the present town, and thus the colony came under British rule. A monument erected where this incident happened commemorates this eventful page of New Zealand history.

Excellent catches of fish can be landed from the pier, or from one of the numerous boats—the deep waters of the harbour, which is about fifteen miles long and reputed to be one of the safest in the world, no doubt accounting for this.

Lyttelton Harbour at Governors' Bay. Blue gum trees in foreground

To reach Akaroa one leaves the city of Christchurch through the suburb of Addington, continuing on past Tai-Tapu, a dairying centre noted for its excellent butter and its notorious stretch of shingly road.

Winding along through Kaituna to Motukarara, the road skirts the foot slopes of the Port Hills on the left, with the extensive stretch of Lake Ellesmere on the opposite side literally alive with thousands of black native swans and pukakis (a species of water hen). This in the season is a sportsman's paradise.

Near here the rider passes through a wire netting gate across the road, part of a fence the full span of the peninsula, which is to prevent the ingress of rabbits at nightfall from becoming a plague on the land, as it is elsewhere in the Dominion. Failure to close the gate at dusk renders the rider liable to a heavy penalty.

Indolent Natives.

Turning now to the left past the lake, the way runs past Birdling's Flat

n the Land of the Maoris.—

or some six miles, until the Maori village of Little River is reached. The natives of New Zealand are ivilised, though rather indolent, and live in European ouses, depending on small plots of cultivated land for livelihood.

As far as this point the road has been comparatively evel, but a mile past the ative village it can be een winding its way up he valley to the 1,500 feet summit of the eights above.

The first few hundred yards of the ascent beyond the village prepares one for what is to follow, amely, a water splash, with a single - figure gradient immediately afterwards.

Steep Gradients.

From now on to the summit is five miles of second gear work, the rack abounding in steep gradients and blind corners.

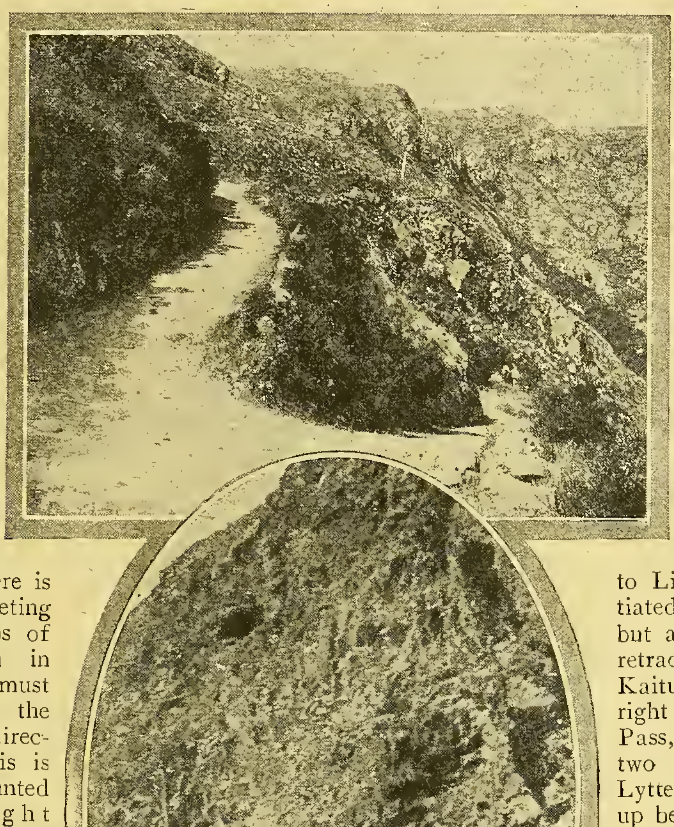
The rule of the road here is eversed, in that on meeting one of the numerous mobs of attle with a horseman in harge, all motor vehicles must ake the outside edge of the oad no matter in what direcion one is travelling; this is or the safety of the mounted man, as the animal might plunge over the precipitous hillside otherwise. Incidentally, owing to the dangerous character of this route, all the roads on the hills are closed to motor raffic after dusk.

The summit reached, the magnificent panorama of Akaroa Harbour stretches out before one with the peninsula of Onawe jutting out in the immediate foreground. In the early Maori wars last century 1,100 of the natives were massacred at this spot, whither they had fled from the surrounding Pas (a Pa is a native stronghold) for refuge.

Akaroa—our destination—can be seen from here across the waters of the harbour in the distance on the right, apparently about twelve miles away, but in reality twenty, the deception being due to the devious route over the intervening hills and bays.

A short distance down the hill brings one to the Hill-top Hotel, where a welcome halt for refreshments is the rule. Leaving the genial host, the next seven miles to the foot of the harbour at German Bay (let us hope the name has been changed now) require extreme caution and good brakes, as the hairpin corners are very severe.

The road now follows along the deviations of the beach through Duvauchelles and other numerous dairying districts, with more stiff climbs and descents, until after one very steep single figure rise and fall Akaroa is reached.



(Top) The Zigzag, near Lyttelton Harbour, a hill which will test the qualities of an engine.
(Bottom) Sumner Cliffs, seven miles from Christchurch.

The time spent here will pass pleasantly enough in boating and fishing, or as a change a delightful woodland stroll may be taken along some of the pretty paths in the vicinity.

As an alternative the return journey is best made *via* the long sharp ascent to the Summit Road, which follows the crest of the hills back to the junction near the Hill-top Hotel. The sea on each side of this track can be seen far below—rather a unique experience compensating for the climb.

The descent back again to Little River must be negotiated with extreme caution, but after leaving the river one retraces one's route as far as Kaituno, where a turn to the right will bring one to Gebbies Pass, a sharp rise of a mile or two to the western end of Lyttelton Harbour, which opens up before one with the Port of Lyttelton on the extreme left and numerous liners wending their way through the Heads in the distance.

Descending the pass, which has a nasty sandy stretch and S bend near the foot, the road winds amidst pretty wooded scenery until Governors' Bay is reached—a favourite picnic resort of Christchurch residents, being only eight miles away by the direct road.

The path which continues is cut out of the hillside and fairly level, alongside the harbour, until shortly after passing the Maori village of Ruapaki on the right, where baskets of native manufacture can be purchased, the Port of Lyttelton is sighted with its ever busy wharves of shipping.

The Zigzag.

The town traversed, the most critical test of the machine's capabilities is before one, the road steadily rising for 1,000ft. until the awe-inspiring gradient of the Zigzag looms above with its several hairpin corners and atrocious surface. Lucky is the rider

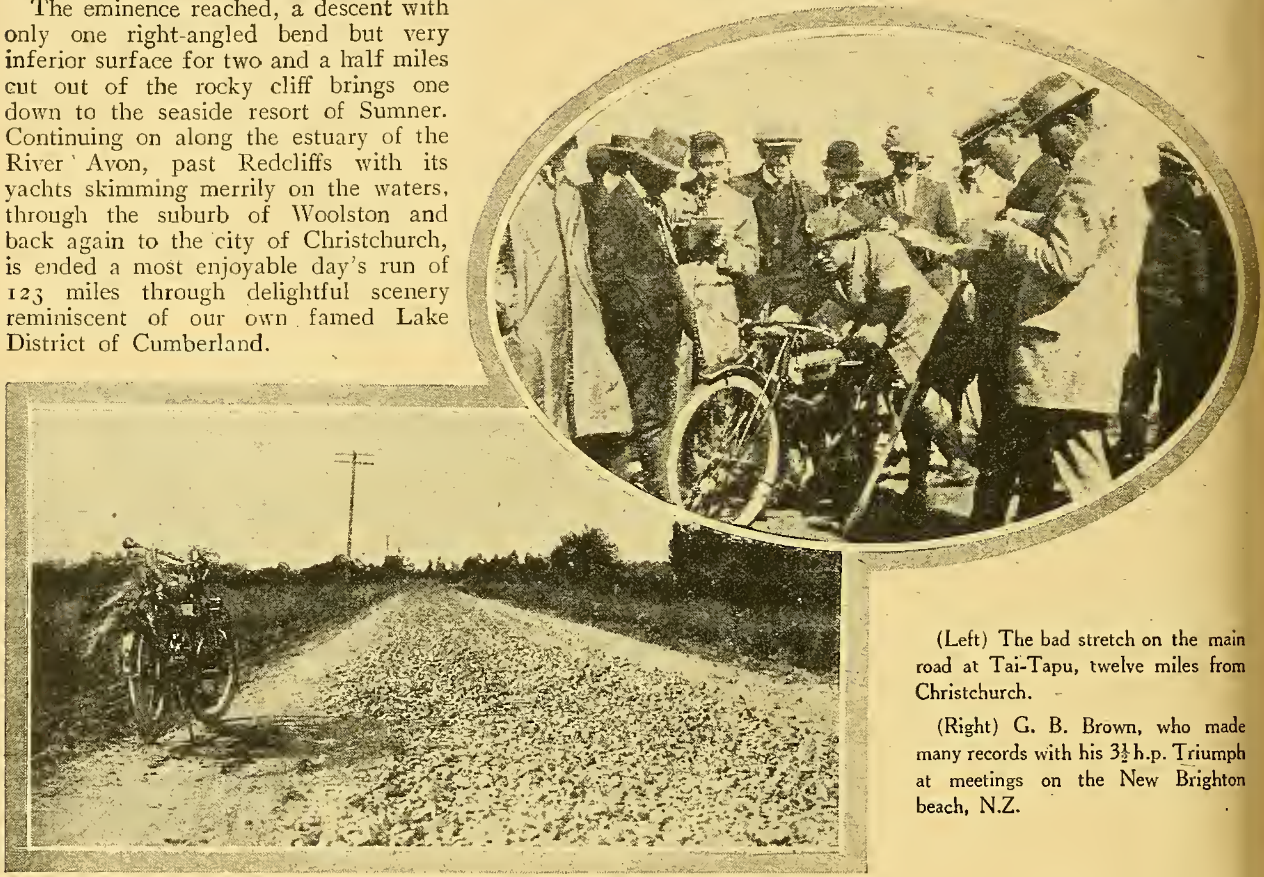
In the Land of the Maoris.—

who negotiates this finishing touch to the trip at the first attempt—even then it will necessitate a very low gear, and skill on the driver's part.

The eminence reached, a descent with only one right-angled bend but very inferior surface for two and a half miles cut out of the rocky cliff brings one down to the seaside resort of Sumner. Continuing on along the estuary of the River Avon, past Redcliffs with its yachts skimming merrily on the waters, through the suburb of Woolston and back again to the city of Christchurch, is ended a most enjoyable day's run of 123 miles through delightful scenery reminiscent of our own famed Lake District of Cumberland.

Incidentally, this route is that used by the Christchurch Motor Cycle Club for their trials, the course being very severe, especially when the weather is at all inclement.

EBORACUM.



(Left) The bad stretch on the main road at Tai-Tapu, twelve miles from Christchurch.

(Right) G. B. Brown, who made many records with his 3½ h.p. Triumph at meetings on the New Brighton beach, N.Z.

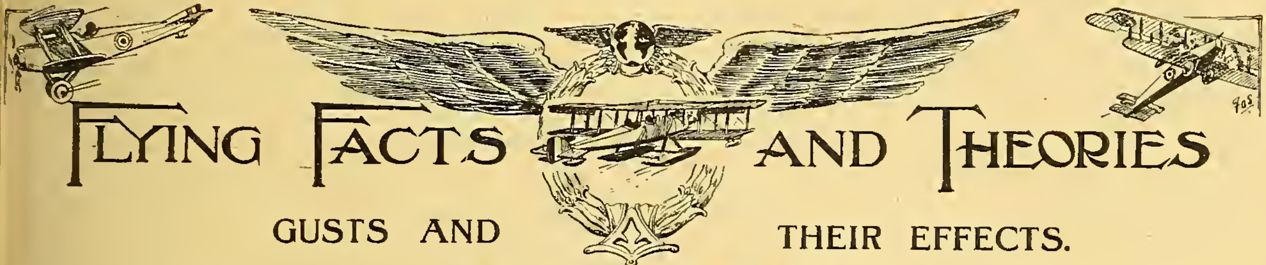
THE A.C.U. AND THE L.C.C.

IT has been known for a long time that the local taxation authorities (in the case of London, the L.C.C.) have strongly objected to exempt motor cycles used for the delivery of goods and solely for business purposes from the licence. In the cases of two tradesmen who applied for the renewal of their petrol licences the authorities refused to recognise their motor cycles as trade vehicles, and refused to renew the petrol permits, claiming £20 4s. on petrol previously licensed to them. The Secretary of the A.C.U. took up the cases, with the result that the L.C.C. now recognise these machines as exempt from the local taxation licence, the claim for £20 4s. has been withdrawn, and the tradesmen have received fresh petrol licences. Previous to these cases being fought the L.C.C. stated that they would only recognise as trade vehicles those in which the sidecarrier frame was brazed to the frame of the motor cycle. The A.C.U. vigorously took up the matter, and pointed out that in no way could this be considered necessary, with the result that the L.C.C. inspector was satisfied that if a steel pin was driven through one of the nuts securing the sidecarrier to the motor cycle frame the vehicle would be considered to be exempt. The case is one of extreme importance, and will doubtless be read with interest by many of our readers.

◆

THE PETROIL LUBRICATION SYSTEM.

A NAVAL officer, in an interesting letter on the petroil system of oiling two-strokes, makes several comments worthy of note. He says the obvious and chief advantage is that it is fool-proof, while its disadvantages consist of either constant over-oiling, with the result that frequent removals of carbon are necessary, or under-oiling, and consequently overheating on hills. The best plan is to use enough oil with the petrol to run on the level and up slight hills without overheating, but this is insufficient for ascending hills with the throttle wide open. Before ascending a steep hill and after ascending it is a good plan to open the throttle fully for about a second, and at the same time switch off the magneto by means of a cut-out switch on the handle-bar. This brings a fresh charge of unburnt oil into the cylinder, and on the two-stroke engine he has used it has prevented overheating and excessive carbon deposit.



FLYING FACTS AND THEORIES

GUSTS AND THEIR EFFECTS.

By W. G. ASTON, A.M.I.A.E.

THERE is a popular supposition and fallacy that "gusts"—that is to say, changes in speed and changes in direction of the wind—are nearly always horizontal. This is no doubt traceable to the fact that near the ground they tend to be more or less so, since the presence of the earth is inclined to absorb their vertical component of motion. In the upper air, however, this influence is removed and gusts are found to favour no one particular direction rather than any other. In short, they come from every point of the compass in the horizontal plane, and in the vertical plane from every hour of the clock, regarding that instrument as a convenient direction post. So far as an aeroplane is concerned, gusts need only be considered in their capacity of changes of wind direction, as this in itself includes the idea of change of speed.

Effect of Cyclonic System of Circulation.

Suppose, for instance, that the wind has an earth speed of 30 m.p.h., and that an aeroplane is flying into that wind. If the speed of the wind momentarily drops to 10 m.p.h., it gives rise to conditions exactly analogous to those in which the aeroplane is supposed, whilst flying through perfectly calm air, to encounter a 20 m.p.h. gust moving in its own direction. For the purpose of considering the effect of gusts, therefore, it will be convenient to suppose that the aeroplane is flying in what is ordinarily still air, and is from time to time attacked by moving columns of air coming from various directions. It will be necessary, however, to remember that the gust which an aeroplane feels is a resultant between the earth-motion of that gust and the speed of the machine itself. Thus, supposing that, owing to heat radiation over some favourable spot, there is, on an otherwise calm day, a vertical, upward-rising column of air, a level-flying aeroplane which meets this column will receive, not a direct, but a diagonal, attack, as set out in the accompanying diagram (fig. 1). Whilst the gust is vertical relative to the earth, it is diagonal relative to the aeroplane. It is important to remember this point, as it might easily be supposed, if an aeroplane is flying in a volume of air which is bodily given a motion of translation upwards, that the aeroplane will undergo no change in the forces acting upon it—the whole system of air and aeroplane will simple rise, and consequently no disturbing effect will ensue. If the moving column of air is vertical relative to the aeroplane such is the case, but if it is diagonal relative to the machine a disturbing effect will take place. The conditions of fig. 1 are set forth rather differently (but with the same result) in fig. 2. The nett effect is that the flow of air, instead of being parallel to the longitudinal axis of the machine, is temporarily (whilst the upward gust lasts) at an angle to it; in other words, the angle of incidence of the whole machine is changed.

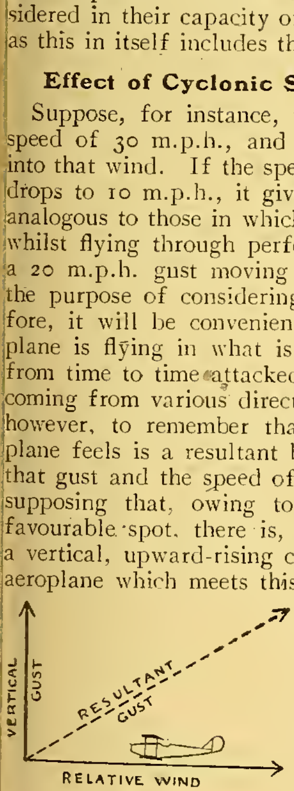


Fig. 1.

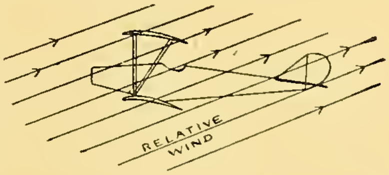

Fig. 2.

Acceleration caused by Gusts.

Since infinite acceleration is unthinkable, it is obvious that a gust cannot be considered to have a definite end or a definite beginning, for at each it must be gradually "smoothed off," as it were, to comply with the surrounding atmospheric conditions. That is to say, in no circumstances can the aeroplane feel the effect of a gust quite instantaneously, since the region of maximum speed in the gust will be immediately preceded by a region (which, however small, will still be there) of less speed. For all practical purposes, however, we can consider the gust to be finite, that is to say, we must allow that if it meets an aeroplane head on it cannot possibly strike both the main plane and the tail at exactly the same moment of time. On an average machine the tail will be at least 20ft. behind the main supporting surfaces, and if a head-on gust has a speed of 20 m.p.h. it is clear that it will take a little over two-thirds of a second to travel from one end of the machine to the other. On the other hand, a gust vertical relative to the machine will strike the whole of it simultaneously, whilst one that is diagonal will have a smaller time-difference than one that is purely horizontal.

In the case of the aeroplane meeting a diagonal gust, the first effect of the gust will accordingly be to tip the nose of the machine upwards, inasmuch as the main planes will get an enhanced lift before the tail is subject to the same influence. Meanwhile the immediate effect upon the aeroplane as a whole will be in the direction of immensely increasing its lift. The drag will also increase in accordance with the proportion of lift to drag, which is characteristic of the particular wing section employed. On the other hand, the air is of much less density than the aeroplane, and is consequently susceptible to much more rapid acceleration. If the gust springs up suddenly—as gusts do—the aeroplane will not immediately be able to decelerate sufficiently rapidly to permit of the rela-

Flying Facts and Theories.—

tive air speed remaining constant. Momentarily, therefore, this speed will be increased. The increased drag effect, consequently, will not immediately be felt, although, of course, it will duly slow the machine down to its normal, or original, air speed. Meantime, bearing in mind the already existing upward pitch, the aeroplane can be considered to be flying at a considerably increased speed and at a sensibly enhanced angle of incidence. The result is that it will climb very rapidly, just as if the pilot had suddenly opened up the engine and provided more propulsive thrust.

At the same time, if the machine has a reasonable degree of inherent fore and aft stability (as nearly all modern types have), it will, of its own accord, and directly the tail comes under the influence of the gust, endeavour to return to its normal attitude relative to the wind; that is to say, its longitudinal axis will tend to set itself parallel to the air flow, as shown in fig. 3. If the gust lasted indefinitely, that is to say, if the gust became a steady relative wind in the direction shown by the arrows in fig. 2, the machine would tend to fly level, *i.e.*, keeping its centre of gravity the same height from the ground (after its appropriate relative speed had automatically adjusted itself) in the attitude shown in fig. 3. Apparently it is "nose down," but only so in relation to the earth, not so in relation to the wind. After a moment or two, however, the gust will pass, hence the machine will once more be flying in still air, but at a greatly reduced angle of incidence. Furthermore, since its speed a moment previously was relative to the gust, its air speed will now also be reduced. The combined decrease of angle and of speed will cause the aeroplane to lose height, but the decrease in drag will at the same time allow it quickly to regain once more its appropriate air speed. Its inherent stability will, also, tend to bring it back to an even keel relative to the wind, as indicated in fig. 4. It is now in the same position as it was before it was attacked by the gust, but it has in the interim undergone three distinct changes.

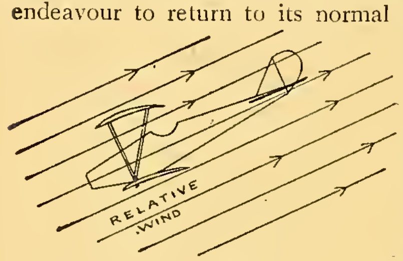

Fig. 3.

1. It has bodily risen owing to the difference between its own inertia and that of the wind, and later descended, for the same reason.
2. It has "pitched." Starting level it has first turned its nose up, and then down, owing to the stabilising action of the tail plane.
3. Instead of flying at a steady air speed, it has first accelerated, and then decelerated, *relative to the air*. Relative to the earth it has done exactly the reverse.

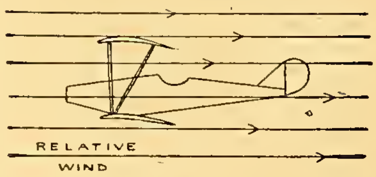

Fig. 4.

It has, it will be seen, been considerably disturbed, therefore, and the magnitude of its disturbance depends, of course, upon the speed of the attacking gust. It may be remarked, in passing, that the disposition of the principal weights along the longitudinal axis of the aeroplane provide a moment of inertia, or a flywheelage, about the transverse axis, which tends to sustain the pitching movement until the tail plane damps it out. It will easily be realised that such a movement, accompanied by a "shoot" upwards which is followed by a similar "shoot" downwards, is calculated to cause personal discomfort. Given sufficient control, however, the pilot can reduce this unpleasant motion very considerably. Hitherto we have been considering only the action which the machine takes of its own accord, but in the elevator the pilot has at his command a means of altering the angle of incidence or attitude of the whole machine according to circumstances.

Gust Disturbances.

When, accordingly, he feels the nose of the machine suddenly rise, as the main planes meet the gust, he will put its nose down by pushing the control stick forward; similarly, when the gust has passed, and he finds himself flying diagonally downwards, he will pull the nose of the machine up. He will thus increase the stabilising effect of the tail plane, and at the same time will not only reduce the angle through which the aeroplane would otherwise pitch, but he will also tend to shorten its pitching duration. Incidentally, he will tend to keep the air speed more nearly constant. It is unlikely that he will be able to keep it quite so, for which purpose he would need to be a very sensitive accelerometer, but he may pretty nearly do so. It is for this reason that most pilots prefer a thoroughly controllable machine for flying in "bumpy" weather. Such a machine readily answers the will of the pilot, and the effect of gusts can therefore be immediately checked, so that less discomfort is felt.

The difference between a stable and controlled machine in this connection may be compared to that between a lifeboat and a destroyer. The former goes over the waves and feels the effect of every one; the latter, if well piloted, rather goes *through* them. Such a comparison is, of course, by no means an analogy.

As I have before pointed out, we are entirely unaffected by velocities; it is only accelerations which disturb us, as one may well prove by going up and down in a fast passenger lift. Pitching provides such an acceleration, but it is less discomforting than the translational acceleration promoted by a quick rise or a quick fall, although, on an aeroplane, it is more immediately visible to the eye.

The change in the angle of incidence that can be caused by a gust results in a change of lift which may be very sharply felt indeed, and the word "bumpy" as applied to the air is by no means a misnomer on occasions. It must be a very severe gust that could force a machine downwards so quickly as to leave the pilot "behind," as it were, since in this case the downward acceleration of the aeroplane must be greater than that due to gravity. On the other hand, much smaller accelerations will give one this impression, which, as far as discomfort goes, amounts to the same thing.

Flying Facts and Theories.—

We will now consider other gusts that, whilst still being in the same vertical plane as the fore-and-aft axis of the aeroplane, can come from different directions. These may conveniently be denoted as resultants by an imaginary clock dial, in which the machine is the centre and supposed to be flying from right to left. The gust that has already been dealt with is, therefore, one coming from somewhere between six o'clock and nine o'clock.

At first sight it would appear that a dead-ahead gust coming from nine o'clock exactly would have no disturbing effect upon the machine other than causing it to rise vertically (in addition, of course, to its horizontal motion of flight). It is, however, in this position that the time-difference previously referred to will make itself most noticeable, and in such circumstances it is clear that the main planes will get the primary addition to lift, so that the nose of the machine will be tilted upwards, followed by a subsequent downward pitching motion. A gust coming from between nine and twelve o'clock will, on the contrary, by decreasing the relative angle of incidence of the main planes, cause them to lose lift, so that the machine will in this case turn its nose down, to be followed by an upward pitch (accelerated by the pilot's control) when the gust catches the tail plane. This case is, of course, the reverse of that which has been previously described, since the aeroplane will now tend to increase its air speed and dive, afterwards climbing and reducing its air speed. Any gust meeting the machine will necessarily tend first to increase its air speed, but its behaviour is dictated by the direction in which that gust comes.

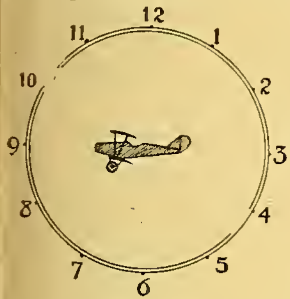

Fig. 5.

Similarly, a gust from between six o'clock and three will reduce air speed, and, as such a gust will tend to affect the tail first, the tendency will be for the machine to put its nose down, afterwards climbing again as the gust passes. One from between twelve o'clock and three will, *per contra,* cause the aeroplane to pitch upwards. It must be remembered, however, that the time-difference dependent upon the angle of the gust enters into the consideration.

The Conservation of Energy.

These motions are independent of this translational effect of the gusts. Those from three o'clock to nine, passing through six, will first lift the machine bodily up, but, when the gust is passed, it will drop again. Those from points on the other semi-circle will do the reverse.

For all practical purposes, whether a machine is suffered to regain its even keel by virtue of its own fore and aft stability, or is maintained in equilibrium by the exercise of the pilot's skill, the passage of a gust leaves it approximately *in statu quo ante.* If the first effect of the gust is to make it gain height, the secondary consequence is that it loses such height in regaining its normal air-speed. Conversely, if the gust causes it to dive, it will be able, when the gust has passed, to transform some of the kinetic energy thus so provided into potential energy, and so regain its previous altitude.

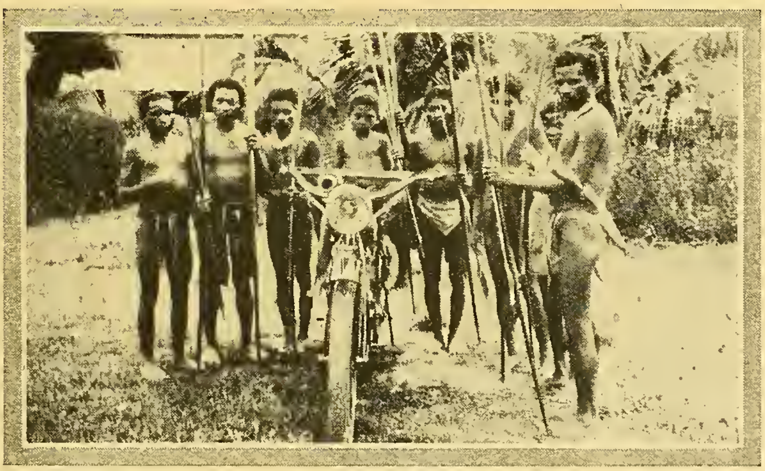
The effect of gust in a horizontal plane will be considered in the next article.

The Motor Cycle in the Philippines.

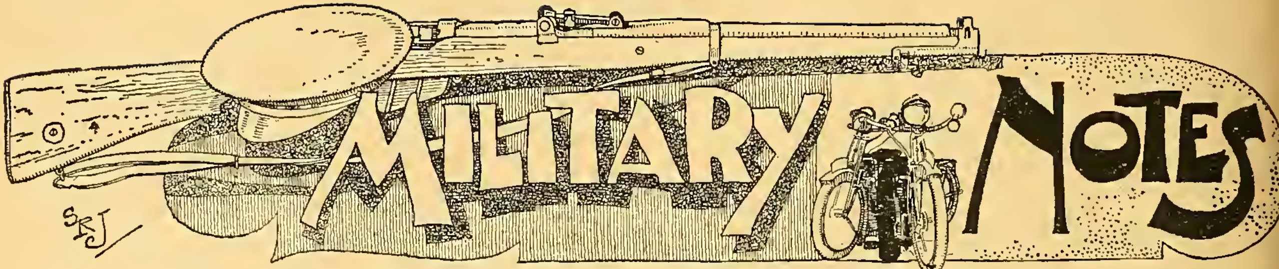
The Motor Cycle in yet Another Sphere previously Ignorant of its Existence.

THE motor has penetrated into the heart of Africa, and into the remotest parts of the globe, and soon the shyest native races will become accustomed to it. The photograph was taken in the Philippines by a lieutenant in the U.S. Service, who says his Indian never failed to create a sensation. Whenever he dismounted and went a short distance away the savages swarmed about the machine like bees on honey, handling the lamp and all the bright fixtures with wonder and fascination. They were somewhat afraid of the engine, as its throbbings shook the frame. One day no fewer than nine of these half savage men were fingering and inspecting the motor cycle, and made no objection—in fact, seemed rather proud—when the white man posed them for a picture.

When the time came for him to go on, the natives ran for a long distance trying to keep up with the machine, but as it gained in speed they stood still, straining their eyes to see it until it became very tiny in the distance, and finally disappeared as the road turned.



Some of that rare species, the almost real savage, inspecting a motor cycle for the first time.



£125 for a Triumph. Notes from Mesopotamia on Spring Forks.

HONOUR FOR SOUTH AFRICAN MOTOR CYCLIST.

We are informed that the late president of the Cape Peninsula M.C.C., Maj. Duncan MacMillan, has recently been awarded the Military Cross.

R.F.C. OFFICERS' CADET WING.

The Royal Flying Corps has recently formed an Officers' Cadet Wing. The age of admission is eighteen, but candidates may apply on attaining the age of seventeen years eight months. The pay is 1s. per day, and the cadet is provided with uniform, messing, and quarters. Application should be made by letter, stating full particulars regarding the applicant, to the Director of Air Organisation, Air Board Office, Strand, London, W.C.2.

£125 OFFER FOR A TRIUMPH.

Sgt. G. S. Cundell, writing from British East Africa, says: "I purchased a 4 h.p. countershaft Triumph from the local agents, Messrs. Childs and Joseph, in May, 1916. I have recently had all kinds of fancy bids for it, the latest being £125, and a practically new lightweight of well-known make thrown in. I have refused all offers, as I understand there will be a dearth of Triumphs in this country (British East Africa) until after the war in Europe. I rode the machine, carrying despatches, in the early stages of the East African campaign, through the jungle and over almost impossible tracks, and a better mount nobody could wish for."

NOTES FROM MESOPOTAMIA ON SPRING FORKS.

The following description of motor cycling in Mesopotamia comes from Cpl. Todd, a despatch rider with the Army Signal Co., and conveys a good idea of the difficulties encountered there. It will be noticed that the weakness of the springs in the forks is a point specially emphasised.

"Writing from this far-off Eastern country one often wonders whether a letter has much chance of being delivered safely; still, I will risk it. Your readers have all heard by now of the appalling conditions out here, and no doubt wonder how it is we manage to make good our duties. At present I am in a cushy billet in —— never mind, and the roads in the district are now in excellent condition; in fact, many stretches of desert are often like a billiard table, but others are just the opposite. The machine I am at present riding is an old Duggy, which has seen just on two years' service, and is still going strong. As there are very few stones about, the tyres last a remarkably long time, and cover a bigger mileage than is possible in England. Also the belts wear an abnormally long time, on account, I believe, of the even running of the engine. One thing the old Duggy requires for this country is a clutch. One often encounters fine quicksands, and all one can do is to drop into low gear, and go all out until it is stuck fast.

The Reliability of the Douglas.

"This machine is also wonderful in its reliability. It is seldom any of us are ever let down through mechanical troubles. But one thing I must mention, and that is the spring forks are not strong enough for the bad conditions here; I do not mean the forks themselves, but the springs. Many gadgets are fitted instead of the usual coil springs, such as leaf springs, etc. We at G.H.Q. all have now an extra spring fitted by our mechanics (who, by the way, deserve great praise for the way in which they have helped to keep these old machines in such excellent condition). It is fitted between the two existing ones, and is very successful in eliminating breakages. The 4 h.p. Triumph is a very fine machine for this 'place,' and gets through almost anywhere. Front fork springs are again a source of trouble, and cannot be easily remedied. Unfortunately, we at this depot cannot manage to secure any of these 3½ h.p. machines at present, but we are all very anxiously awaiting some of them."

500,000 AMERICANS.

Mr. Daniels, Secretary of the American Navy, has announced that there is now sufficient tonnage to land half a million men in France this spring.

A BRITISH ARMOURED CAR OFFICER ARRESTED IN RUSSIA.

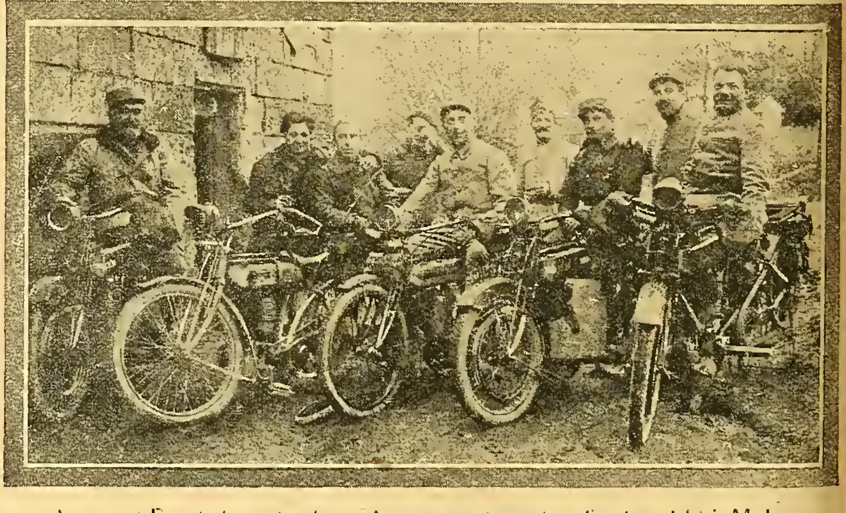
Commander Dye of the British Armoured Car Detachment, was arrested on February 2nd in Petrograd. He was charged with being the owner of two bombs, which, it appeared, had been overlooked while packing souvenirs of the fighting. After communicating with the Embassy, and receiving assurances, the police released him.

WRIT SARCASTIC.

"Tank Driver" writes: "In your issue of January 31st you publish a letter from Cpl. Richardson, M.T., A.S.C., in which he asks several questions, among these being, 'Who drive the Tanks?'

"As a member of the Tank Corps since its inception, and a Tank driver of sixteen months' standing, I wish to inform Cpl. Richardson that not a single Tank in France is driven by the M.T., A.S.C., whilst in action.

"I would like to ask Cpl. Richardson in return, 'Who move the heavy guns when it is too dangerous for the M.T., A.S.C. to do it?'"



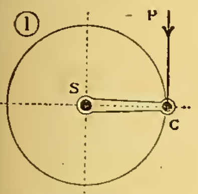
A group of French despatch riders. Among these (second reading from left) is Madame Gourand Moriss. She is one of the very few women D.R.'s serving with the French Army The mounts are Triumphs and B.S.A.'s.

THE MEANING OF TORQUE.

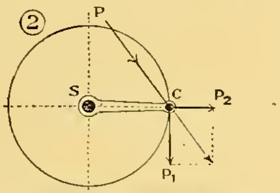
A Discussion and Explanation of a Widely Used but Often Misunderstood Term.

TORQUE means turning moment. Considering fig. 1, if we have a force P acting at right angles to crank CS, we subject the shaft S to a turning moment or torque of P × CS. Measuring P in pounds and CS (distance from centre of crank pin to centre of shaft) in inches, we have P × CS lb.-in. Sometimes it is convenient to state a torque as the equivalent force acting at a radius of 1ft.

Instead of P acting directly at right angles to the crank, we may have a state of affairs as fig. 2, in which case, in order to get the effective torque, it is necessary to resolve force P into its component parts CP_1 and CP_2, the former acting at right angles to the crank and producing the torque, whilst CP_2 represents the pressure on the crankshaft bearings in the direction shown.



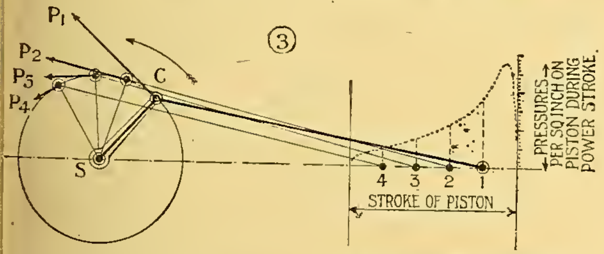
To illustrate the meaning of torque.



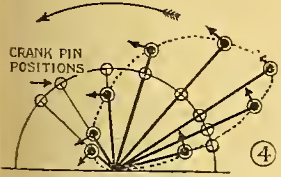
The effective torque in a reciprocating engine.

As regards the motor cycle, the question of torque interests us in two directions—(1) the torque developed at the engine shaft, and (2) the torque developed at the back wheel.

The character of (1) is quite definitely determined by the type of engine used in driving the motor cycle. In all cases (motor cycle) this torque is intermittent and variable, the degrees of continuity and variability of torque being modified according as there are one, two, three, or four cylinders to the engine. The greater the number of cylinders the better the torque, but four cylinders, even, is likely to remain for some time just outside the pale of normal motor cycle practice.

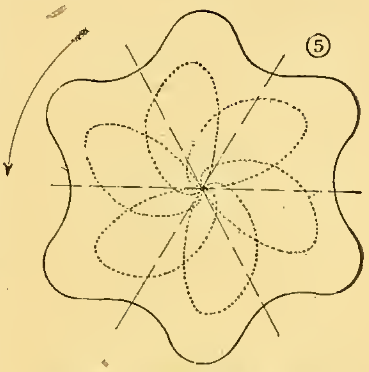


The development of the torque in a single-cylinder engine.



As regards (2), torque developed at the back wheel, this can be made the same within negligible limits for any of the above types of engines, it being the function of the flywheel to effect this result.

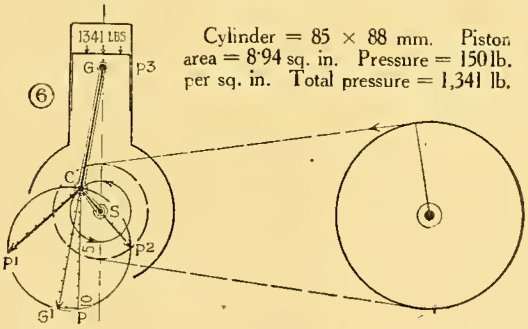
Given *the same effective torque at the back wheel* in both a single and a multi-cylinder machine, there is only one point where difference would be observable in riding the two machines—the single-cylinder machine would be inferior in accelerating power owing to the very heavy flywheel with which it would be fitted. In this regard it may be mentioned that some single-cylinder engines have a feeling of "life" and "power" which is quite misleading, and is the result of having under-weighted flywheels. In these cases even torque at the rear wheel is sacrificed to give rapid acceleration. Perhaps such a machine has advantages for short distance racing, but for touring work, where the hazards of greasy roads, etc., are to be encountered, a machine with an even torque at the rear wheel is to be preferred.



Showing the torque developed in a twelve-cylinder engine firing at even intervals, the torque produced by individual cylinders combining to give a resultant torque as shown approximately in the black line curve.

Torque in Single and Multi-cylinder Engines.

Figs. 3 and 4 show how torque is developed in a single-cylinder engine. There is, of course, only one power stroke every two revolutions of the engine, and during that power stroke the torque varies, being zero at the beginning of the stroke and rising to a maximum before the middle of the stroke, then falling away to zero again. Fig. 3 shows the variation in torque by assuming the crank to remain the same length, the arrow lines then showing how the force tending to turn the crank varies for different crank positions.



Cylinder = 85 × 88 mm. Piston area = 8·94 sq. in. Pressure = 150 lb. per sq. in. Total pressure = 1,341 lb.

CP = Total pressure on piston = 1,341 lb.
CG^1 = Compression connecting rod = 1,408 lb. = pressure on crank pin.
CP^1 = Force acting at right angles to crank = 1,110, giving a torque of 1,110 × $1\frac{11}{16}$ = 1,875 lb.-inches = 156 lb. at 1 foot radius.
CP^2 = Pressure on crankshaft bearing = 856 lb.
G^1P = Pressure of piston on cylinder wall at P^3 = 234 lb.

The Meaning of Torque.—

In fig. 4 it is assumed that the force tending to turn the crank is constant, whilst the crank assumes different lengths for the different torques developed. This method of showing the variation of torque is useful when multi-cylinder engines are under consideration. Fig. 5 gives an idea of the torque developed in a twelve-cylinder engine with even firing intervals. It will be seen that even in this instance the torque is variable.

Figs. 6 and 7 show a simple method of obtaining graphically the torque developed in a cylinder for any position of crank during power stroke, assuming that one has an indicator diagram or knows the pressure in the cylinder at the moment under consideration.

⑦

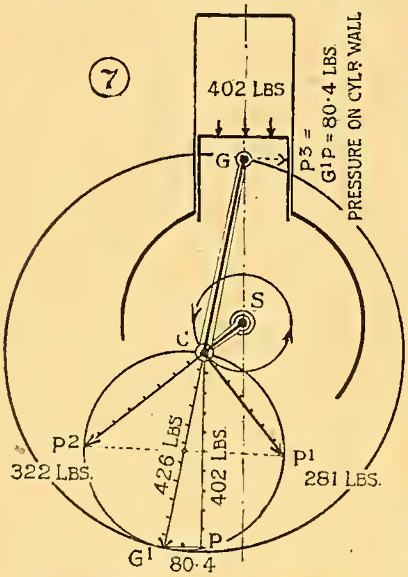


Diagram to show how the different forces may be ascertained.

The diagrams are practically self-explanatory, fig. 7 showing the construction.

It is necessary only to bear in mind that CP represents the total pressure in the cylinder, *i.e.*, pressure per sq. in. × area of piston in sq. in. After constructing diagram as shown, divide CP into ten parts. Each part will then have a value $\frac{\text{Total pressure}}{10}$. Divide out the lines CP_1 and CP_2 to the same scale as divisions CP, and the values of CP_1 and CP_2 can then be ascertained.

Average Torque.

In a motor cycle engine we have seen (1) that torque is developed only during one stroke in four, and (2) that this torque varies both with the pressure in the cylinder (or cylinders) and with the position of the crank.

If, however, we are told of a certain engine that it develops a torque of "28 lb. at 1ft. radius" when running at 3,000 r.p.m., we know that this refers to *average* torque. This may be defined as that torque which, constantly applied, would have the same effect as the intermittent and variable torque under consideration.

Average torque may be
- (*a*) Calculated from i.h.p.
- (*b*) Calculated from m.e.p. and engine capacity.
- (*c*) Calculated from b.h.p.
- (*d*) Obtained by direct reading from brake test.

The values of (*a*) and (*b*) would be identical, as also would be those of (*c*) and (*d*), but the two latter would have the less actual value, just as, and in the same proportion that, b.h.p. is less than i.h.p.

The relation between h.p. and torque is given by the following formula:

$$\text{Torque} = \frac{63,024 \text{ h.p.}}{\text{r.p.m.}}$$

where torque is in lb.-in.

In the case just mentioned, where torque is 28 lb. at radius of 1ft., we have

$$\text{Torque} = 28 \times 12 \text{ lb.-in.} = 336$$
$$\text{R.P.M.} = 3,000$$
$$\therefore 336 = \frac{63,024 \text{ h.p.}}{3,000}$$
$$\text{H.P.} = \frac{336 \times 3,000}{63,024} = 15\cdot9$$

The relation between m.e.p. and torque is given by

$$\text{Torque} = \frac{V \times \text{m.e.p.}}{4\pi}$$

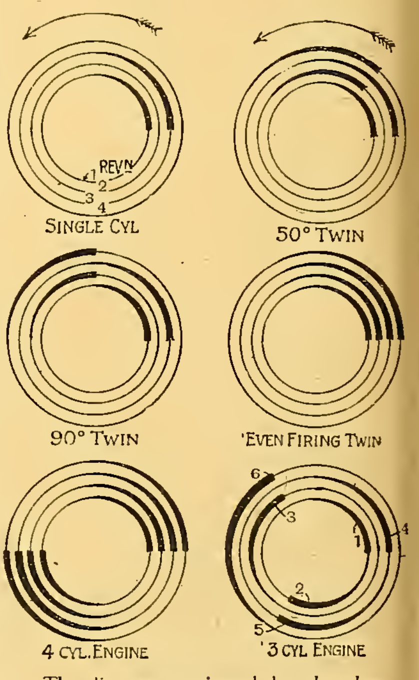
where V = engine capacity in cubic inches.

Example.—Engine capacity 60.3 cubic inches, m.e.p. = 75.

$$\text{Torque} = \frac{60\cdot3 \times 75}{4\pi} = 360 \text{ lb.-in. } (4\pi = 12\cdot56)$$
$$= 30 \text{ lb. at radius of 1ft.}$$

If the mechanical efficiency or $\frac{\text{b.h.p.}}{\text{i.h.p.}} \times 100 = 85\%$, then the effective average torque would be $\frac{85}{100} \times 30 =$ 25.5 lb. at 1ft. radius.

The remaining diagrams show the variation in the intervals between the power strokes of different multi-cylinder engines, and give an idea as to the intermittent nature of the torque developed at the engine shaft.



The diagrams are intended to show how the intervals between the power strokes vary in one, two, three, and four-cylinder engines. The circles represent successive revolutions, and the thickened line shows the power impulse in any revolution.

Notes on curves published with description of the Harley-Davidson 1918 model, "The Motor Cycle," Jan. 3rd, 1918.

An indicated h.p. curve was calculated from m.e.p. curve, but found to be identical with that

The Meaning of Torque.—

marked b.h.p., showing an error in either curve or description.

Judging that the torque curve would have been obtained by actual brake test, I made a calculation of h.p. from the torque curve to get at the true b.h.p. values. The new curve was found, however, to show greater values than the i.h.p. curve at certain points, though considerably less at others.

An explanation should be given with such curves as these if they are to be intelligible. In the case of b.h.p. it should be stated whether the gears are in operation or not.

The following particulars would perhaps be most suitable for the ordinary motor cyclist:

Maximum i.h.p. at various speeds.
Maximum b.h.p. at engine shaft.
Maximum b.h.p. at back wheel with first gear in.
Maximum b.h.p. at back wheel with second gear in.
Maximum b.h.p. at back wheel with third gear in.
Torque and m.e.p. could be calculated if wanted.

ENGRO.

The Norton Programme after the War.

DURING a recent visit to the works of the Norton Motors, Ltd., at Aston, Birmingham, we were informed by Mr. Norton that they have decided to adhere to the single-cylinder policy, and to confine their efforts to three models in solo mounts, in place of the former six or more different varieties.

(1.) The T.T. Sports model, 3½ h.p., belt drive, with variable pulley, for the speed merchant.

(2.) The Utility mount with a 3½ h.p. T.T. engine of special tune, all chain drive and three-speed countershaft gear, for the average rider.

(3.) The Utility mount with a "big four" engine and all chain drive, three-speed countershaft gear, for very heavy solo or sidecar work.

The last two models will carry the well-tried Sturmey-Archer three-speed gear as hitherto.

Thus this firm of long-stroke specialists will cater for all classes of riders without staging a mixed lot of models.

It is interesting to find that Mr. Norton has been carrying out experiments with aluminium alloy pistons for some time past. He has given a fair trial to a number of different alloys, and, so far, only one brand has withstood the test; others invariably ran tight at speeds over 25 m.p.h. and knocked loose at the gudgeon pin holes. The one successful alloy piston has stood up well, and gives promise of wearing as well as the ordinary type of piston. Whether this will form a feature of the three "after the war" models, already mentioned, is not yet decided; no doubt it will be left to the purchaser's choice.

A recent publication of the firm is a small handbook of driving hints; it contains concise instructions and advice, together with specifications of the Empire or military model Norton, and is well worth perusing by anyone interested in single-cylinders. Messrs. Norton will be pleased to forward copies on receipt of stamp (1d.) to cover postage.

The National Motor Cyclists' Fuel Union.

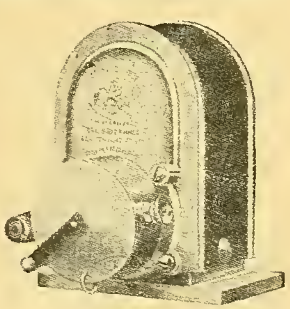
WE recently had a conversation with Mr. A. W. Torkington, chairman of the National Motor Cyclists' Fuel Union, who, in view of the fact that some misapprehension exists in the minds of the general public as to the objects for which the N.M.C.F.U. was formed, has asked us to make the matter quite clear to our readers.

Letters have appeared in various journals which make it evident that the writers believe the Union is endeavouring to extort concessions from the Petrol Control Department which are denied to other people. The Union has even been credited with the desire to use force if necessary. Members of the N.M.C.F.U. have joined themselves together in a body in order that they may have their individual cases properly put before the Government. Owing to difficult housing conditions many munition workers have to make awkward cross-country journeys in order to get to their work at six o'clock in the morning, and they are entitled, in such circumstances, under the Petrol Restriction Order, to an allowance of petrol for their motor cycles. They are not asking, and have not asked, for a collective grant of petrol; that point has been clearly laid down in the interview which their chairman had with the Petrol Controller, Sir Evan D. Jones, his deputy, Mr. Webb, and the other Departments concerned, who have treated the Union with both consideration and sympathy.

This is the best answer to all the criticisms which have been levelled against it, because had the Union commenced its career by demanding such privileges for its members it would not have received either consideration or sympathy from the Petrol Control or other Departments.

To judge from some of the letters the chairman has received, it would appear that the writers consider that the munition worker should be treated worse than other people, and that he had no right to petrol at all.

Members who are entitled to petrol under the Motor Spirit and Gas (Consolidation) Order, and who apply to the secretary, Mr. W. Ellis, 70, Abingdon Street, Derby, will now get it, but they must be careful to give all the necessary details, as otherwise the Controller cannot grant a licence. In a few days full particulars of the position and recommendation forms will be in the hands of all the secretaries of the Union.



The latest model "Lion" magneto manufactured by the Britannic Electrical Co., Ltd., Birmingham.

GREENWICH TIME.

Feb. 28th	6.5 p.m.
Mar. 2nd	6.8 ,,
,, 4th	6.12 ,,
,, 6th	6.16 ,,

Summer Time.

The clocks are to be put one hour forward this year on the 24th of next month, and they will be put back again on September 29th. This gives us five weeks longer of that inestimable blessing, more daylight, than we had last year.

Motor Cycling in South Africa.

Motor cycling in South Africa appears to be suffering but little from the war, if the membership of the leading club is anything to go by. The C.P.M.C.C. has recently received several additions to its membership lists, and the sport as a whole seems to be in a flourishing condition.

Joy Rides for Wounded Soldiers.

This is another of those things, of which we have here seen the last, that still carries on at the Cape without any restraint. Meetings and rides are frequently held, and the men appear to appreciate the action of those motorists who take them out as much as they used to in England.

Sidecar Combination v. Train.

On a recent occasion the rider of a 1917 Powerplus Indian, with a sidecar loaded to its capacity with camping outfit, raced the No. 19 Union Pacific passenger train from Cheyenne, Wyoming, to Granite Canyon, a distance of twenty miles up hill. Although the train was drawn by two powerful engines the Indian motor cycle outfit won by ten minutes. The race was followed with interest by the passengers on the train, who cheered the driver heartily when he pulled up at the crossing at Granite Canyon.

Employment of Discharged Soldiers and Sailors.

The employment of discharged soldiers and sailors, both now and after the war, is a matter that has already received much discussion, and has formed an excuse for the creation of many and various committees. Although there is in existence a committee specially for the purpose of dealing with those men connected with the motor industry before the war, this is a matter that is also dealt with by the Institution of Automobile Engineers, which is now hoping to be able to prove of considerable assistance to various Government Departments in this sphere as need arises.

Imports and Exports.

The value of the imports of motor cycle parts in January amounted to £3,138.

EXPORTS.

The exports still maintain a comparatively high level, though lower than December's figures.

	1916	1917	1918
Number of machines	836	872	514
Value of motor cycles parts, tyres, accessories	£70,065	£79,130	£52,998

Famine in Motor Cycle Spokes.

A South London motor cycle agent informed a correspondent that he spent a whole morning last week making a round of the London factors in quest of spokes for motor cycle wheel building. One well-known house had not even a dozen in stock! Another only stocked the heavier gauge, for light car wire wheels, and no factor had any stock of or near the gauge required. Finally, he obtained a few dozen from a retail depot.

Special Features.

THE MEANING OF TORQUE.
IN THE LAND OF THE MAORIS.

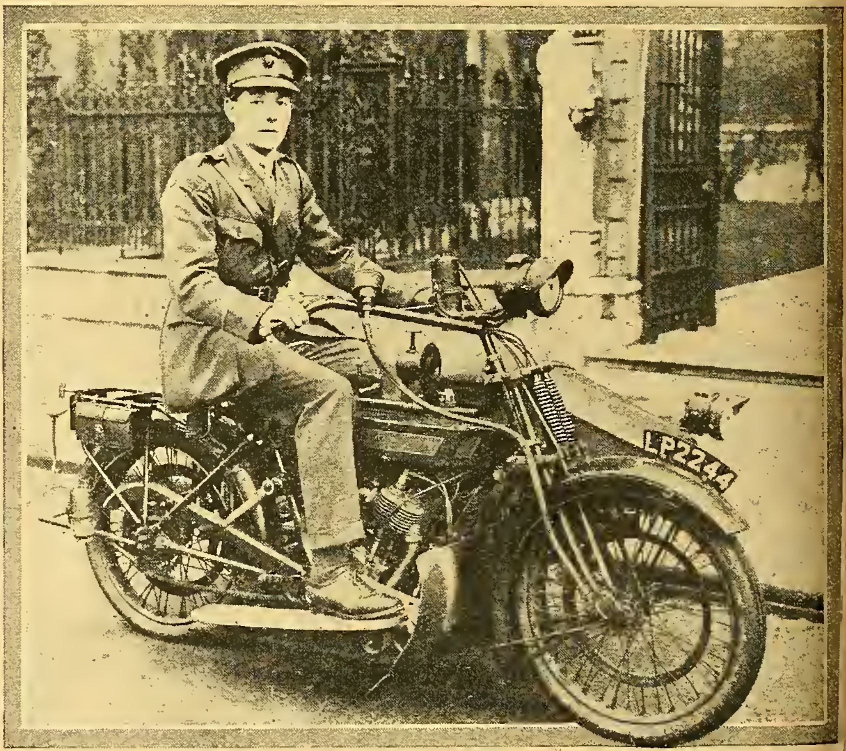
The Institution of Automobile Engineers Graduates' Prize.

This prize has this year been awarded to Mr. C. Pole Wedmore for his paper on "Valve Timing," and a second prize has been awarded to Mr. H. L. Towns for a paper on "Welding." These prizes are awarded annually to the graduates reading the best papers during the previous season.



A. J. Davies, late lieutenant London Irish Rifles, who lost his leg above the knee through wounds received in action at Vimy Ridge. He purchased the Enfield 6 h.p. combination last September, and found no difficulty whatever in learning to drive, although it was his first experience with a motor cycle. He uses the machine daily on Government work, and, owing to the gear being hand-controlled and the hand-starting, he finds the machine extremely easy to handle even in the most congested traffic.

A Passenger Attachment.

A police witness at Willesden recently tated, "The defendant was driving a motor cycle and sidecar, with a young ady attached."

The Local Taxation Licence Rebate.

The Auto Cycle Union, in its endeavour to help the individual motor cyclist, has been in communication with the Treasury concerning the question of obtaining a rebate on the local taxation licence paid by such motor cyclists as have been debarred from using their motor cycles on and after November 1st, 1917, owing to he Motor Spirit Restriction Order. The ecretary requests us to insert the reply:

> "Sir,—I have laid before the Lords Commissioners of His Majesty's Treasury your letter of the 6th inst. enquiring as to the return of a proportionate part of the motor car licence duty to those persons who, having paid such duty for the year 1917, were debarred from using their motor cars or motor cycles on and after 1st November, 1917, by the operation of the Motor Spirit Restriction Order, No. 2, 1917.
>
> "In reply, I am to state that their lordships have no power to accede to this suggestion.
>
> "I am, Sir, your obedient servant,
> "(Signed) J. L. HEATH."

On the other hand, an owner of a motor cycle is not liable to pay motor car licence duty for the current year unless he is actually using his machine, and if he is using it exclusively for the purpose of any hospital or ambulance work, or any work undertaken by agreement with the Government in connection with any Naval or Military purposes, he is entitled under Section 14 (2) of the Finance Act, 1916, to claim repayment of the whole or a proportionate part of the duty.

The secretary of the Auto Cycle Union will be pleased to advise owners how to prepare such claims.

Mr. W. Williamson Convalescent.

All friends of Mr. W. Williamson, of the Williamson Motor Co., Coventry, will regret to hear that he has been seriously ill with pneumonia and pleurisy. He was unconscious for eleven days and nights, but was able to get up last week, and is now well on the way to convalescence.

Advisory Committee of Business Men.

An Advisory Committee of Business Men to the new Department of Overseas Trade is in process of formation, and will be announced shortly. The temporary headquarters of the Department will be at 73, Basinghall Street, E.C.2, to which personal letters for Sir Arthur Steel-Maitland should be addressed.

The Coming Season.

The longer days and the improving weather will naturally make those of us who cannot use our motor cycles yearn for peace and plenty (of petrol); but this year we must grin and bear it, stick it out, and put up with a hundred and one inconveniences, discomforts, and privations, which are as nothing to those our brave soldiers Overseas have to endure. It is only by so doing that we can emerge victorious over the Hun.

After-the-war Models.

Most firms have attractive post-war propositions either actually on the road or designed and ready to be manufactured as soon as possible after hostilities cease. Only the other day we came across a brilliant young engineer who has had much experience with motor cycle engines. He is at present in the M.T., and is engaged in hauling about heavy artillery, and is kept busy in maintaining caterpillar tractors. Nevertheless, he has had time to design a complete motor bicycle fitted with an even firing V twin two-stroke engine, possessing many novel and original features, and a new and ingenious ignition apparatus. Both will shortly be described in *The Motor Cycle.*

The Institution of Automobile Engineers.

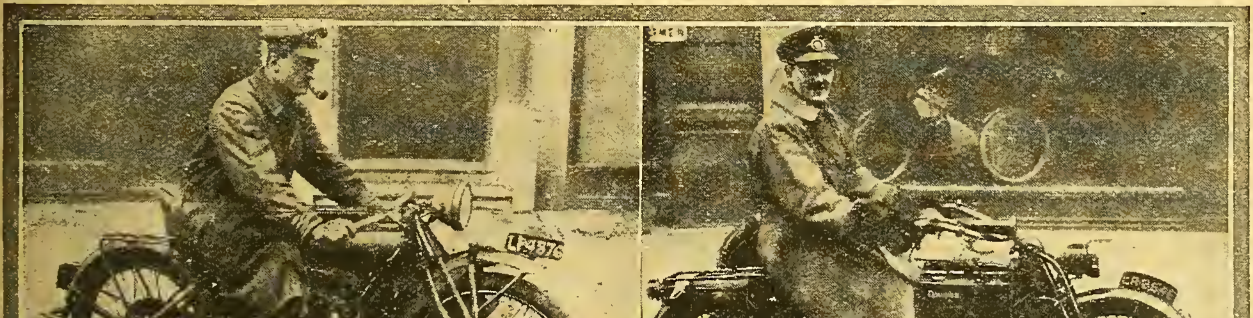
At the last meeting of this body, held on the 13th inst., Mr. Ernest A. Savage, the Librarian of the City of Coventry Public Library, read a paper on the "Utilisation of the Data of the Automobile Industry through Bureaux of Information." The paper was very well received, and is of special interest at the present time in connection with the recently announced proposal of the formation of research associations.

American Sympathy.

At the meeting the following telegram was read from the Society of Automotive Engineers (of America): "Expressing great admiration for your effective and magnificent work in the war, the members of the Society of Automotive Engineers assembled in annual meeting to-day send cordial greetings and felicitations. In the common cause for democracy we send assurance of co-operation to the fullest extent.—CLARKSON."

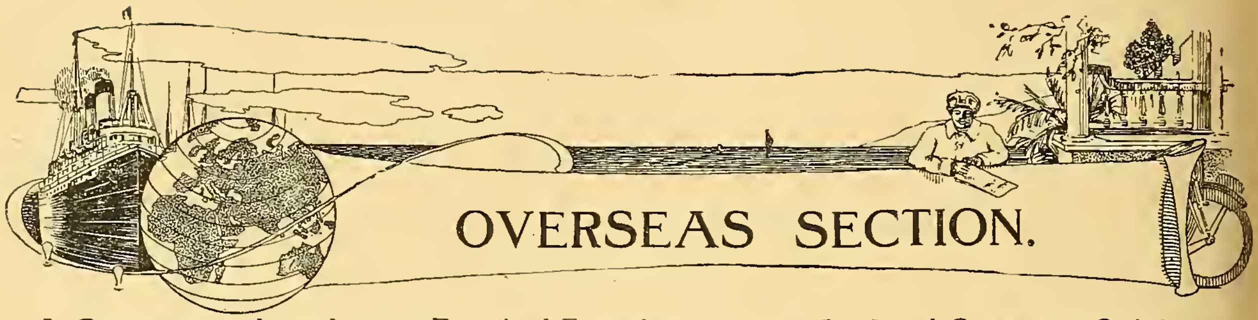
Women's Legion and Lady Motor Cyclists.

We have received a letter from Lady Londonderry, President of the Women's Legion, from which we have pleasure in quoting: "A cutting from *The Motor Cycle* has been sent me, in which there is a letter from Miss Violet Moore, stating that she could obtain neither information nor work regarding the Women's Legion drivers. May I point out for the information of future correspondents that the headquarters of the Women's Legion Motor Drivers' Section are at 15, Pall Mall East, where all information can be obtained from the Commandant, Miss Ellis. The Legion is responsible for providing all the drivers for the A.S.C. and R.F.C. for home service. Miss Moore applied to 115, Victoria Street, and she was referred to Miss Ellis. I find, on enquiry, that no communication has been received from her at that office. This section is a military branch and directly under the control of the War Office."



MEMBERS OF THE A.C.U. MOTOR MESSENGER DETACHMENT.

(Right) G. L. Fletcher, manager of the London depôt of Messrs. Douglas Brothers, Ltd. He was a well-known competition rider from the very earliest days of the manufacture of Douglas motor bicycles. (Left) Vivian Olsson, an old member of the Motor Cycling Club, who has competed in numerous important A.C.U. and M.C.C. competitions. He joined the R.N.A.S. in 1914, and was attached to the Armoured Car Squadron under Commander Sampson, R.N., in France, where he did excellent work, serving with the squadron some eighteen months. Both these men are now doing excellent work with the newly instituted Auto Cycle Union Motor Messenger Detachment.



OVERSEAS SECTION.

A Commentary based upon Practical Experience and a Study of Overseas Opinions.

The Overseas Lightweight. MANY Overseas riders possess an erroneous and somewhat narrow conception of lightweight machines, as is illustrated by their constant reference to "buzz-boxes" and such like designations, but, in spite of this prejudice, it is obvious to anyone that the lightweight is a highly commercial proposition, possessing no inherent defect which limits its sphere of adaptability to the conditions of a settled country. It must be admitted, however, that most makers of small two-stroke machines have not hitherto paid much attention to Overseas demands. The idea generally has been to capture the low price market, and, because machines of this type particularly lend themselves to cheap production, cheapness and the lightweight have progressed, more or less, hand in hand.

A machine cannot be made cheaply to stand up to the requirements of the Overseas riders, and, if the lightweight is to succeed Overseas, its makers must aim at larger markets, which will enable them to sell a stronger article at existing prices. By cheapness we refer not so much to the price of the machine as to the quality of the minor fittings. The general practice has been to fit a good engine and gear box, and proceed forthwith to take it out of the purchaser by utilising pedal-cycle fittings. We have undertaken journalistic tests of numerous two-strokes excellent in every respect, except for the flimsiness of such fitments as mudguards, saddles, handle-bars, and controls. These appear to have been stuck on as an afterthought, and are of hopelessly inferior workmanship compared with that of the power unit throughout, whereas—particularly for Overseas use—the quality of the minor fittings largely determines the satisfaction the machine will ultimately give.

This point cannot be rammed home too firmly. The Overseas rider expects a good power unit, and will get it any way, so that the quality of the minor fittings will weigh very heavily in his judgment. He is not going to purchase a lightweight if by so doing he is assured of mudguards which will shortly rattle to bits, controls which will break or swivel round the bars, handle-bars which assume the semblance of the "extreme touring" variety, owing to his having hauled the machine forcibly out of a mud hole. and hubs that will give trouble after the first rainy season. We do not mean to imply for one moment that such defects characterise the present day two-stroke, but we do say that they have characterised many of the cheaper variety which have found their way to Overseas markets, and that this state of affairs has not a little to do with the prejudice existing towards lightweights in many parts of the world.

Details that Count. IT is, of course, impossible to eliminate the cheap machine, and the rider who buys a mount of unknown make simply because the price tempts him naturally takes his own risks. But, on the other hand, there are numbers of lightweights made that belong to a higher order, and yet which fall sadly short of Overseas requirements simply on account of the makers having "spoilt the ship for a ha'porth of tar," as it were. We have a good engine, good gear box, good frame, good spring forks, but the whole effect is spoilt by the fitting of mudguards of the wrong design—mudguards with flimsy points of attachment, and permitting insufficient wheel clearance, so that even a light fall of snow renders the machine unrideable. Similarly an inferior saddle is perhaps fitted, with the result that vibration and pot-holes form the essence of one's first riding impressions. Fit the same machine with a good saddle and one could hardly believe it to be the same machine, for of all types of mount the lightweight demands a saddle of superior quality, without which even the best of material throughout the remainder of the machine will fail to impress the rider favourably.

* * *

As a Recruiting Agency. GIVEN a lightweight built in every respect in accordance with Overseas requirements, there is no doubt that it would meet with an immense reception in all quarters of the globe. It would not, of course, take the place of the heavyweight, as it would meet the requirements of a different order and be patronised by a different class of rider. We do not for one moment approve of the common statement that lightweights are suitable only for city use in our Overseas dominions. Given a lightweight of the proper type, the demand for it would be almost universal. Sold at a little over half the price of the heavyweight and of proved reliability, it would be a medium whereby scores of new recruits would be initiated into the pastime, to buy heavier mounts later on, perhaps, but who would not have contemplated taking up the pastime at all had it not been for the light machine.

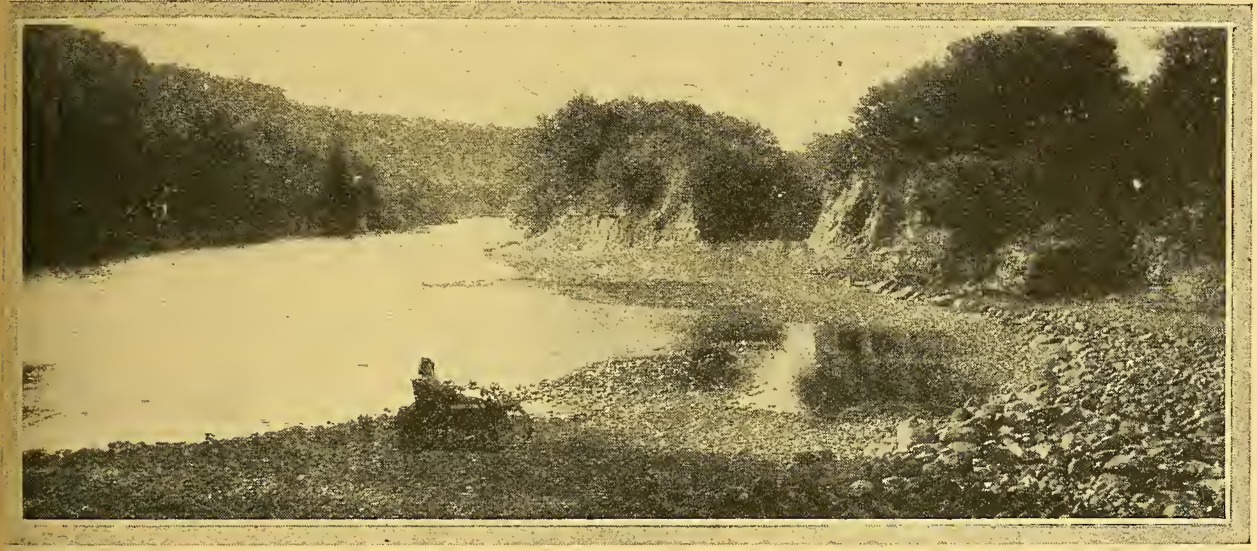
Nor would the lightweight be scorned by the old hand: for making journeys from one plantation to another, for twenty-mile trips to and from the settlement, even for serious riding when the conditions are such as to render the handling of a heavy mount laborious. We ourselves have ridden lightweights under the most trying conditions, and are convinced that, with the addition of a simple three-speed gear, heavy flywheel, and hand-controlled clutch, the type is suitable for almost any conditions. It will stand pro-

verseas Comments —

nged low gear work as well as—generally better than -a more powerful engine, and, though naturally slow, ne is not as a rule out for speed when the conditions re so perverse as to tax the staying powers of the igine.

By the above we do not suggest that the small mount ould even hold its own in side-by-side riding with the eavier variety; we know that the latter is preferable, ut we are equally convinced that there is ample room or both.

The question remains, then, whether any reputable rm of lightweight manufacturers is prepared, after e war, to make a special bid for the Overseas market. n England the demand for the simple two-speed ghtweight will probably hold good, and in this country the conditions do not entirely demand those features essential for Overseas use. The third gear would be superfluous, the extra heavy flywheel unnecessary, the hand clutch, similarly, could be dispensed with for the sake of simplicity, so that, though a special model for Overseas use in the way of heavyweights may not be necessary, it undoubtedly is necessary in the case of the lightweight. In the heavyweight the Overseas rider requires what we require at home, but he requires it more urgently; in the lightweight he wants everything we want and a little more ere the type can be regarded as a practical proposition. It remains, then, for some maker of note to tackle the problem of the Overseas lightweight in all earnestness, and there is no doubt that, given proper administration at the other end, he will reap a rich reward.



The Addo Drift—a typical specimen of the drifts in South Africa, which in time of flood are roaring torrents.

A Selection of Letters from Readers scattered all over the World.

Overseas Machines, a Sporting Challenge, and German Goods.

From "ARTIFICER," Siege Artillery, France: "The arrival f the January 3rd 'Blue 'Un,' with its particularly varied ontents, has put the finishing touch to a resolve made onths ago, to write a note of appreciation regarding your ournal.

"In commencing, I may as well state my identity as an)verseas man—an Australian to wit—serving with one of he heavy batteries on the Western Front: one who has aken particular interest in articles appearing from time to ime in *The Motor Cycle* which dealt with Overseas requirements, conditions, and markets, also the lack of representaion of British motor manufacturers in Australia, the latter esulting, as you are well aware, in the seizure of the Colonial market by American trade.

"At present American motor products, such as Indian, Harley-Davidson, and Reading-Standard in the motor cycle ine, and Ford, Studebaker, Overland, Dodge, and Buick, re now rife at home, and bid fair to continue even *après a guerre*, unless British manufacturers awake.

"Apart from the big difference in initial outlay of a nachine, and the quick, cheap replacement of spares, the nethod of doing business that the Yank adopts to impress upon you that a Ford or an Indian will save time and trouble, and bring you in more pounds sterling per day, scores every time.

"However, time will show, and I hope that after the war we shall see U.K. on Colonial roads in as large numbers as U.S.A.; but to effect this, design, price, and business methods must be revised, and standardisation in each class adopted.

"So far as motor cycles are concerned, the W.D. Triumph at present used out here nearly fills the bill for an all-round solo mount, the only objection being front forks and brakes. Abolish the front rim brake and fit an additional one on the back wheel—internal expanding for preference—to act in an emergency, the extra weight being worth it; scrap the forks and fit Mark II. Druids or else Mark I., with Terry links, a wider guard in rear, and at £65-£70 it will sell like hot cakes.

"While talking of Triumphs, I would say a word or two in connection with a 'sporting challenge,' in which a 4 h.p. Triumph, chain-driven and otherwise as per W.D. pattern, and an 8 h.p. Jap-Excelsior were matched recently. The challenge was sporting enough, but the action of the Excelsior man in appearing with a Montgomery sidecar against the other's heavy Gloria, which the Triumph firm have fitted for years, and scooping up the laurels for himself, seemed scarcely as sporty.

"To have qualified for the title of 'sport,' he should have uncoupled and effected an exchange of sidecars, if they were interchangeable or could readily be made so—at least he could have offered—and I fancy if the Excelsior had had to lug along the coachbuilt sidecar there would have been a different tale to tell afterwards.

"As it was, the 4 h.p. with its heavy load making the performance it did, proved itself more than a match for the 8 h.p. twin and featherweight sidecar, taking into consideration the difference in c.c. and load.

Overseas Comments.—

"Sidecar machines to suit the Colonial conditions and requirements should be somewhat after the military model New Imperial, with a decent twin engine of about 750-1,000 c.c., 28in.×3in. interchangeable wheels all round, a reliable three-speed box, dual clutch control, and three brakes on rear wheels of the internal expanding and external contracting type; internal expanding on rear wheel and car wheel to act simultaneously from pedal on right side, and a Bowden-operated external contracting brake controlled from the handle-bar to act as an emergency brake on the driving wheel. Incorporated electrical equipment optional, and either sprung frame or efficient seat-pillar (spring), and a strong kick-starter.

"Just at present there is a slight argument in your columns anent the German goods question. May I assure the Ives, Little, R.O.W. coterie *and* others that they may be thankful they are not in the Army—for soldiers they can never be—and that the Army is very thankful, too? Their sort are not worth wasting bad words over. F. Jones's letter provided me with a quarter of an hour's merriment; he should join a literary society before rushing into print, and then take first packet off to Liepzig or Mannheim, where a stray English bomb would bring him to his senses.

"*Re* the 'four-cylinder spoil-the-sport' theory, no, never! Ride a Henderson or a F.N. four and you have got the poetry of motion; but a one-lunger is the best for a healthy T.T. or to shake off a bad liver.

"Discussions such as this, 'Centrifugal Force,' 'Flying Facts and Theories,' technical articles, and 'Ideas,' all go to make the journal a big 'two-pennorth.'

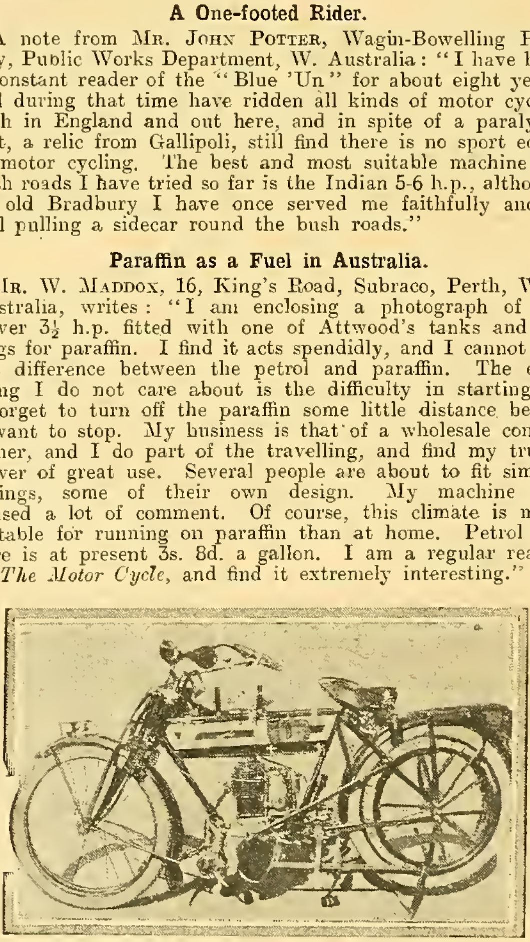
"In conclusion, may I express appreciation of the general lines on which your paper is run—its tone, its originality and fairness?"

A One-footed Rider.

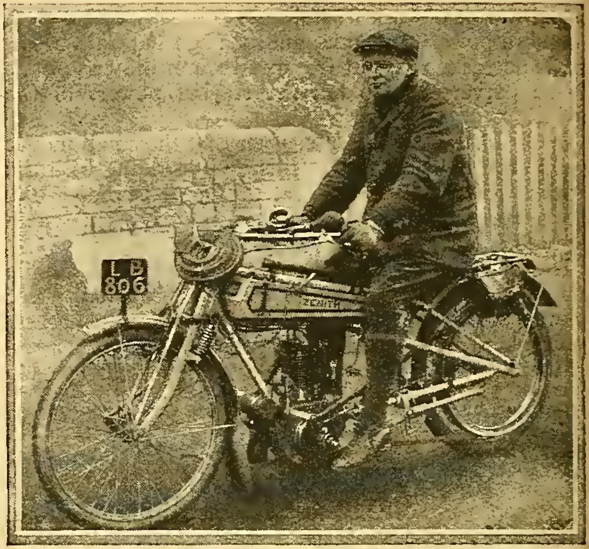
A note from Mr. John Potter, Wagin-Bowelling Railway, Public Works Department, W. Australia: "I have been a constant reader of the "Blue 'Un" for about eight years, and during that time have ridden all kinds of motor cycles, both in England and out here, and in spite of a paralysed foot, a relic from Gallipoli, still find there is no sport equal to motor cycling. The best and most suitable machine for bush roads I have tried so far is the Indian 5-6 h.p., although an old Bradbury I have once served me faithfully and is still pulling a sidecar round the bush roads."

Paraffin as a Fuel in Australia.

Mr. W. Maddox, 16, King's Road, Subraco, Perth, West Australia, writes: "I am enclosing a photograph of my Rover 3½ h.p. fitted with one of Attwood's tanks and fittings for paraffin. I find it acts spendidly, and I cannot tell the difference between the petrol and paraffin. The only thing I do not care about is the difficulty in starting, if I forget to turn off the paraffin some little distance before I want to stop. My business is that of a wholesale confectioner, and I do part of the travelling, and find my trusty Rover of great use. Several people are about to fit similar fittings, some of their own design. My machine has caused a lot of comment. Of course, this climate is more suitable for running on paraffin than at home. Petrol out here is at present 3s. 8d. a gallon. I am a regular reader of *The Motor Cycle*, and find it extremely interesting."



A Rover running on paraffin in West Australia.



A SLOPING TANK OF 1909.

Many motor cyclists are under the wrong impression that the sloping tanks, such as are fitted to the A.J.S. and Allon and other modern machines, are quite new in design. The photograph, taken in 1909, shows a Zenith which had a tank giving the desirable low riding position.

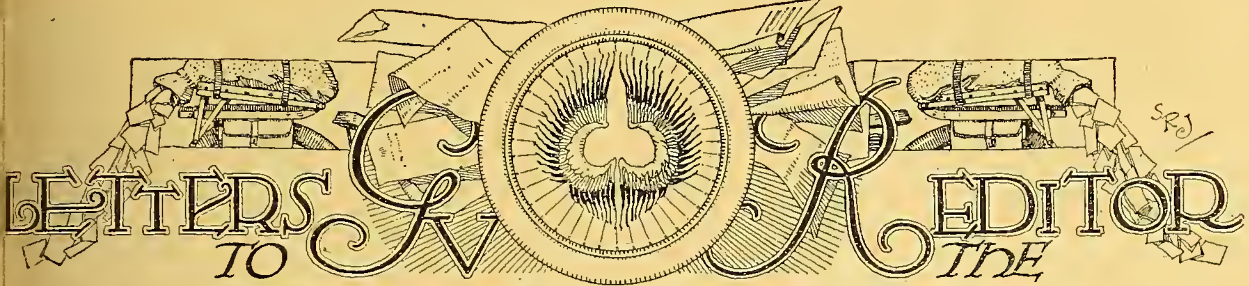
Remarks on Singles and Belt Drive in Canada.

Mr. Wm. Greenwood, Toronto, Canada, sends the following interesting letter: "I am very much interested in *The Motor Cycle*, as it keeps one up to date with the improvements that are from time to time bringing machines as near perfection as any 'mechanics' can make them. I have been in the cycle business since 1874, when I was agent for Messrs. Dixon Bros., blacksmiths, Hulme Hall Lane, Miles Platting, Manchester. To look back to that date—and having ridden practically more or less every machine, not missing the Unicycle (an American product), where the rider sat inside the wheel—I was acquainted with Dan Rudge before he invented the ball bearing [Ball bearings were invented long before Rudge's time.—Ed.], having met him at Mr. Clarke's, maker of the Cogent bicycles, in Wolverhampton. I have sold over 200 motor cycles in Toronto, 130 of which were Triumphs. When the war commenced of course we could not get any supplies, and this fact put us out of business.

"The English manufacturers cannot understand why they cannot do business in Canada. There are several factors against them—*e.g.*, their prices; the inability to get parts in case of breakage; and, in some cases, the Canadians look with disgust on the single-cylinder machine, which falls short when put to serious usage on our 6in. deep sand roads; also the vibration is more pronounced than in the twin.

"Another big factor against motor cycles here (and this does not operate in England) is that almost everybody has enough land behind his dwelling on which he can store a small or large car easily, and a car can be bought here now for a less price than we can sell a 4 h.p. Triumph, fully equipped with sidecar, etc. It is all right for a man and his wife, but when additions arise, then they cannot be left at home, and the motor cycle and sidecar makes a poor substitute. I am convinced the future will furnish a small family car, and its advantages over the sidecar are obvious, especially in bad weather. We have now ten or twelve inches of snow to pull through, with the thermometer at 14° to 20° below zero. There are hundreds of cars pulling through it, but I have seen only one motor cycle and sidecar, and that was a four-cylinder Henderson.

"Sometimes I take my Triumph Junior out, but when I get into snow a few inches deep I have to walk, and this I can do with the engine running and the belt slipping. I should advise the English manufacturers to keep their eye on the four-cylinder Henderson, as it is certainly a wonderfully reliable machine, and its freedom from vibation is remarkable."



LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address

RONT BRAKE DESIGN.

Sir,—We notice in your issue of the 14th inst. an article n front brake design. Our machine is mentioned, amongst thers, but we should like to point out that we were the irst to design and adopt the type of brake referred to; nd as proof of this we may mention that our motor cycles itted with this brake were exhibited at the 1912 show. The lesign met with a considerable amount of adverse criticism t the time, but was followed by other firms at a later date.

LEA AND FRANCIS, LTD.,
R. H. LEA, Managing Director.

LAMINATED SPRING SYSTEM FOR THE REAR WHEEL.

Sir,—With reference to the spring frame designed by Pte. A. F. Markham, and described in your issue of February th, if Pte. Markham has patented this arrangement since November 23rd, 1916, it would appear to be an infringement f our patent of that date, No. 109,887.

In view of the fact that you suggest existing machines night be modified, we think it would be advisable to intimate o your readers that we should consider the application of he design to existing machines as an infringement of the bove-mentioned patent.

F. E. BAKER, LTD.
FRANK E. BAKER, Director.

ARRYING AN ACCUMULATOR.

Sir,—"Ixion" was complaining two or three weeks ago hat he could not find any place on an ordinary solo machine vhich was steady enough to carry an accumulator. May I oint out to him and the rest of your readers that a spring rame is not necessary? I described my device in a letter o you last autumn, and I trust it will become popular. There is no patent about it. It continues to give me complete satisfaction, and it will do the same for any man or voman who has decent saddle springs, and will keep an ppreciable amount of weight on the saddle all the time. The accumulator is carried in a box that is hung by rod from one of the back corners of the saddle, sliding up nd down on a guide rod fixed to the frame and steadied by radius rod, anchored near the top of the engine.

W. REGINALD WILSON, M.A., M.B., B.C. Cantab.

ADDLE CLEARANCE.

Sir,—I take the liberty of using your journal to express my opinion of British motor cycle frames with regard to saddle clearance.

Prior to the war I owned several motor cycles, and almost all were British and of the best make. British saddles are very comfortable, but I regret to say that British motor cycle manufacturers do not allow the riders of their machines the full benefit of that comfort, because the saddle comes into contact with the back mudguard when riding over bad roads, just where comfort would be most appreciated. This is due to inadequate clearance between saddle and rear guard or carrier on some makes.

This inconvenience does not exist in American machines, for the top tube of the frame is dropped differently from the British, thus affording a full movement of the saddle. I recognise that some British manufacturers have this point under consideration; but many have omitted to probe the matter, or perhaps have preferred to sink the saddle to make the saddle line level with that of the top tube of the frame

H. FROCOURD.

THE POSITION OF THE CLUTCH.

Sir,—It was with considerable surprise that I read on page 150 of your February 14th issue a statement by your contributor "Chinook" that it was better for the clutch to run at half engine speed than full engine speed, especially as this was prefaced by remarks on weight saving.

Will "Chinook" give us his reasons for such an assertion, as a reference to elementary mechanics shows that in order to obtain the lightest possible clutch it must be placed at the point of highest speed and least torque, namely, the engine-shaft? In this position the friction moment is at a minimum, and consequently the spring pressure and clutch parts can be lighter than anywhere else in the transmission line. Also the reduction of spinning weight has a beneficial effect on gear changing—a fact well known to car people, but mostly overlooked by motor cyclists.

Another feature is that, if the clutch is incorporated with an outside flywheel, the revolving portions form part of the total weight of the flywheel, with a consequent saving in the overall weight of the machine. Also, what noticeable effect can the position of the clutch have on the distribution of weight, as "Chinook" considers? A modern 4 h.p. touring machine weighs about 250 lb. Engine, clutch, and gear box account for about 100 lb. of this total, and as a decent clutch should weigh less than the magneto, its location cannot have anything but a negligible effect on the position of the centre of gravity of the machine.

May I refer those who require proof of the foregoing remarks to the February issue of your sister journal, *The Automobile Engineer*, where, on pp. 54-9, they will find an article explaining the first principles of clutch design?

E. CAUDWELL, A.M.I.A.E.

PETROL FOR THE MUNITIONEER.

Sir,—I am sure that I have not yet seen in *The Motor Cycle* any "narrow-minded laments" as regards the petrol restrictions.

Probably J. Carroll, Lt., B.E.F., does not know that motor cycling is practically a dead letter, while private cars owned by "someone" still run about by the score. I know of many cases, and will relate one.

A large manufacturing firm before the war could not afford to invest in even a motor cycle, but since has a large private car weighing a matter of 34 cwt. Now this car runs empty from W. to W.—a matter of eight miles—every morning to bring back one man; takes him back at night and returns empty—a matter of sixteen miles per day. Moreover, the train service is quite handy. I questioned a police inspector as to this, and he told me that the police did not want to stop everybody, and, besides, the user of the car was a manager.

I have no sympathy with anyone who laments over joy-riding being stopped, but why one class and not another? One thing I, in common with other motor cyclists, would like to know is, Is shortage of petrol so serious as J. Carroll, Lt., and others say?

I may say I have a petrol licence, but how is it that I can, if I wish, get petrol without a licence? We over here know full well that there is a war on. If there is any need to stop pleasure motoring—well, do so by all means; but why when no need?

I hope Lt. Carroll will not take this letter as a criticism of his good self, but as an honest question whether there is a petrol shortage and a serious one.

Widnes. PRIMUM-MOBILE.

[There *is* a shortage, and it is serious.—ED.]

AMERICAN AND BRITISH MOTOR CYCLES.

Sir,—"Moveo," in his article in defence of the American, is obviously writing from an experience of the two or three most refined Americans over here. I took "Chinook's" original article to refer to American practice in general, and when one examines the samples of the lesser lights amongst the Americans over here, and notes their glowing crudities, it is obvious that he is pretty well right.

"Moveo" refers to a "Big Four" which requires the gudgeon pin to be driven out before the cylinder can be removed. I understand that the phrase "Big Four" was originated by Mr. Norton, and applied by him to his 82×120 mm. engine. One begins to doubt the extent of "Moveo's" engineering experience if he were unable to remove a Big Four Norton cylinder without first removing the gudgeon pin. I am using a 1917 model Big Four Colonial model at present, and I think I could present "Moveo" with the entire machine, in small pieces in a box, inside the time that he could dismantle the engine alone of one or two Americans I know.

Many of my motor cycling friends are members of the medical profession. It may interest "Moveo" to know that several of them, after a spell of riding Americans, have reverted to British machines. Their reasons for the reversion are singularly unanimous.

1. Unreliability after the first workshop tune has worn off.
2. Rapid wear of essentials after six months' to a year's hard work.
3. Constant attention to a multitude of flimsy gadgets, which, despite the alleged better balance of the American engine, persist in shaking loose, curious to relate!

These three main reasons are quite enough for the man whose machine receives the minimum of attention and the maximum of work.

M.B.

Ystalyfera.

ANOTHER LIGHTING PROBLEM.

Sir,—I had similar requirements to Mr. R. Percy, and solved them simply and satisfactorily. I wanted a no-trouble lighting set for my two-stroke on my daily journey of six miles each way through dark, steep, and narrow lanes.

I had a wooden case made to attach to the sloping top tube of my machine, and in this I put my accumulator, size 4 volts 20 amps., price 12s. 6d. (1915), bought at an electrical gadgets shop in Bull Street, Birmingham—just a plain standard line. The head lamp was an F.R.S., with an adjustable focus, and a readily removable lamp socket which enables one conveniently to throw a light where required when mending punctures, etc., at night. The tail lamp was a smart little thing, beehive shape, obtained from Brown Bros., and carried a 4 volt bulb obtainable at any flashlight-monger's. The head lamp I adapted to take a similar bulb by making a device from an old bayonet cap socket to receive the screw bulb type of contact. (My description of this was published in *The Motor Cycle* some two years ago.)

In this way I obtained a lighting set with the following good points:

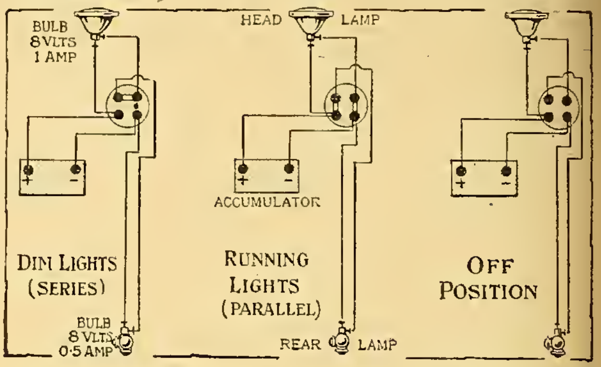
1. Wide suffused light for foggy nights or a long penetrating beam for speedy runs, instantly convertible.
2. A beam of light which enabled me to read the inscription on a penny at thirty-five yards—this with a bulb of .4 amp.
3. Bulbs are interchangeable, so if that in the head lamp fails one can borrow from the tail lamp to get to the next town.
4. Any old village stocks these flashlight bulbs.
5. As a test, my accumulator just lasted out for three weeks at half an hour a night, though in regular use I leave it on charge all day every other week.
6. The set has been in regular daily use from the spring of 1915 until the end of last year, and it has never given me a minute's trouble: the accumulator has therefore been shaken and dithered for over 10,000 miles without receiving any injury.

What more can anyone want?

ALLON.

Birmingham.

Sir,—In reply to Mr. Percy's lighting query, I think his 12 c.p. rather high, and should suggest 8 c.p., or he will find trouble in getting an accumulator to fit on his cycle, as it would have to be rather large to last any time. Herewith I give connections that will work well, using one of Lundberg's series—parallel and off switches—which can be obtained from A. P. Lundberg and Sons, 1-6, Paradise Passage, Islington, London, N.

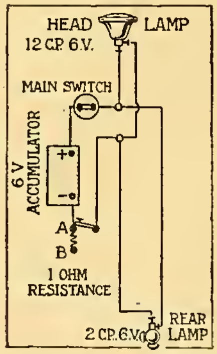


The switch can be fitted on the accumulator box, and makes a neat job.

An eight-volt 40, 60, or 80 amp.-hour accumulator should be used according to the room available. The rear lamp should be eight volts, 0.5 amp. 4 c.p. taking only half the current of the front lamp and giving less light, and a resistance may be inserted if necessary about 8 or 10 ohms; a lamp of this sort takes one watt per candle-power, or one volt × one amp. per candle-power. Osram bulbs are good and reliable and are guaranteed. He can obtain exactly what he requires at the Economic Electric Ltd., 10, Fitzroy Square.

L. J. HEALE.

In answer to Mr. Percy's enquiry *re* wiring for solo mount in your issue of the 7th inst., possibly the enclosed diagram will help him.



For ordinary running purposes the key is in position A; for leaving the machine while in town the key is placed at B, thus putting the one ohm resistance into circuit. This will reduce the candle-power of the front lamp to three, and that of the rear lamp to a half candle-power.

I should suggest that two candle-power is the least one could use for running in the normal way (I refer, of course, to the rear lamp). Anything less would insufficiently illuminate the rear number-plate.

In answer to Section 2 of the letter, I should suggest a 60 amp. hour six volt accumulator, as this would give approximately fifty hours continuous light if the lamps indicated were used, and would also be comparatively light and small. If expense is no object, I should suggest an Edison accumulator.

Sections 3 and 4 are already answered. Section 5, the Osram lamp is a very good one. Half watt lamps should be used.

I regret that I am unable to offer any suggestion as to where he might obtain these accessories.

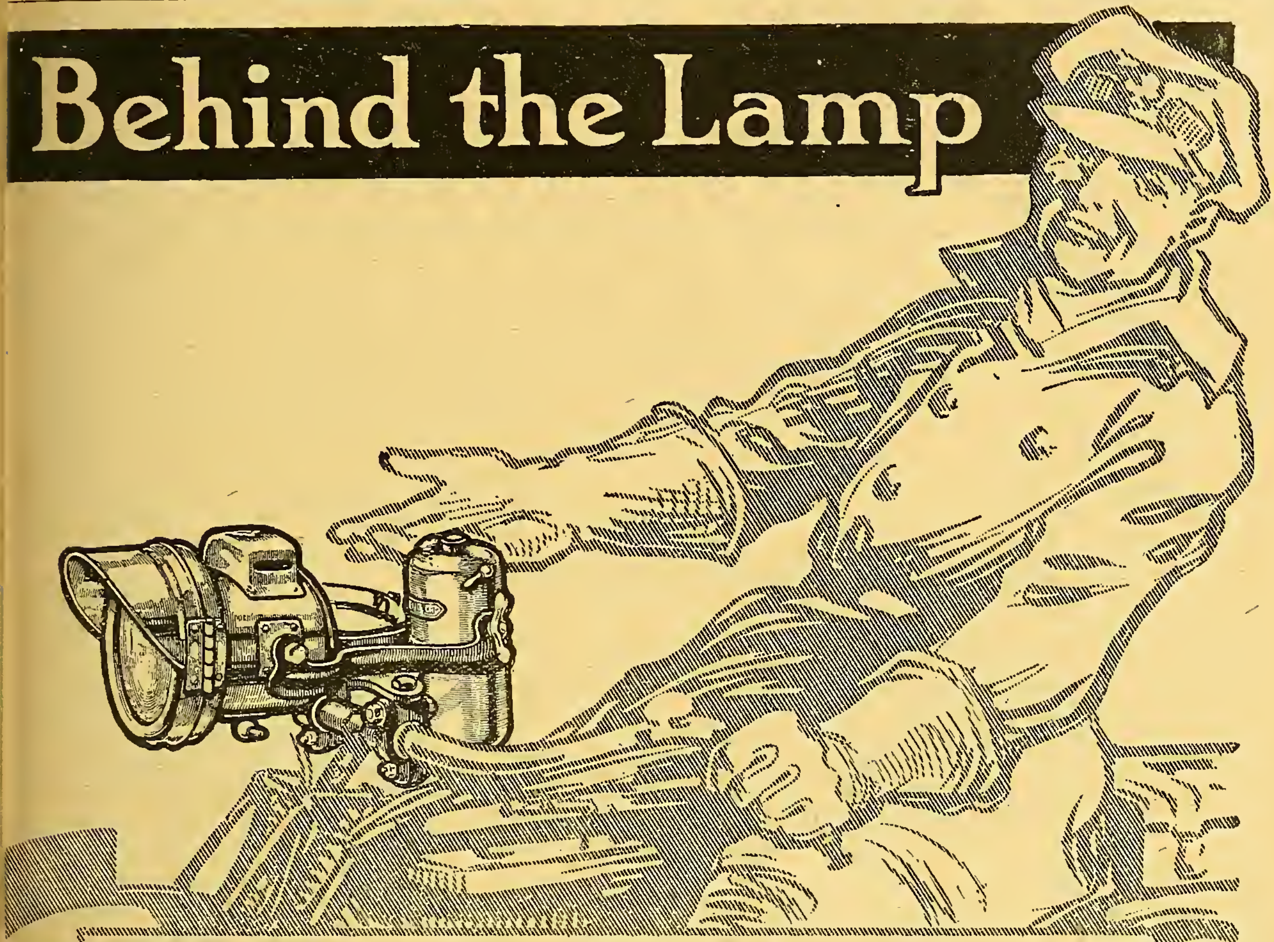
WILBERFORCE DURELL.

GOODS MADE IN GERMANY!

Sir,—I cannot let your controversy on "Goods made in Germany" pass without dipping in my oar. As an old reader, I may say that I consider you have made a tactical error in printing your "Important Notice" weekly, as in years to come you will not be able to keep to the sentiments expressed therein. I thoroughly agree with the letter from your contributor, Mr. Ives, except for the fact that he stopped his copy of *The Motor Cycle*. However, this is a personal fancy. *Chacun à son goût*, and, given time, you will no doubt recover from this unquestionably staggering blow.

I may say I am not entirely a peace crank or a "no conscription" maniac, having joined H.M. Forces before the outbreak of war, and living as I do in the hope of at least another twenty years' service.

Behind the Lamp



Behind the Lamp, the rider—in front, the danger! There, in a word, you have the reason why this item of equipment should be selected with the utmost care. The danger is no longer danger if the headlight really points the way. But the Lamp of inferiority will never fulfil that purpose as the

MILLER

will—hence, hesitate before you buy another. The Miller Catalogue tells you all about all Miller Models, and the Motor Cyclist who has used them, or the Retailer who sells them, will tell you more than we can of their merit.

H. MILLER & Co. LTD. Light Specialists, BIRMINGHAM

On a good thing

We have known men who have fancied themselves on a real good thing when buying a "cheap" tyre—we have known the same men realise from bitter experience that no tyre is "cheap" which is not good.

We claim that the

JOHN BULL

is superlative, that the Trader who sells it and the rider who buys it are both "on a good thing" every time, and we once again point to that average back wheel mileage (proved by hundreds of riders over all sorts of roads, in all sorts of weather)—an average of 4,996 miles—as evidence.

And the compressed rubber tread is the secret!

Coal-Gas.

COAL-GAS-propelled MOTOR VEHICLE OWNERS should adopt as a standard lubricant

COAL-GASTROL

C. C. Wakefield & Co., Limited, having caused exhaustive tests, extending over 1,000 miles, with Coal-Gas as the motive power, to be made by their expert to discover the best grade of lubricant to be used with COAL-GAS, have no hesitation in recommending

WAKEFIELD
Coal-Gastrol Motor Oil

as *the* oil for this purpose. Increased power, smooth running, and absence of carbonization are features prominently associated with the use of this lubricant. COAL-GASTROL is a CASTROL grade with the Wakefield guarantee.

C. C. WAKEFIELD & Co., LIMITED
(Sir Charles Wakefield, Bart., Governing Director).
WAKEFIELD HOUSE, CHEAPSIDE, LONDON, E.C.2.

Why is it that manufacturers will paint their names in huge letters on the tank? I seldom remember seeing Rolls-Royce in enormous letters on the bonnets of cars. Nothing ooks worse, and although one can always paint out the name on a new machine, this should not be necessary. There are one or two machines, such as the Rover and Triumph, the manufacturers of which refrain from this regrettable practice; but they are the exception.

In all sincerity, I would say, is it not time we had reverse gears fitted to heavy sidecar outfits? They would be invaluable for turning in a narrow road and backing out of the garage, and although the spectacle of a man riding his machine solo and putting in the reverse by mistake would not be other than amusing, this need not occur with care.

TAMPION.

c/o G.P.O.

Sir,—I am going to write you my opinions, such as they are, on the controversy that rages in your paper over the notice you so praiseworthily publish on "Goods made in Germany." If you think fit, please print them. They are crudely put and roughly written, but on Active Service one is excused much.

I can quite understand that the advisability of publishing such a notice is a debatable question: there are points for and against that have to be carefully considered before coming to a definite conclusion.

Mr. Ives's views apparently are these. He would wish to prevent Germany from regaining her strength after the war because she has used to such fell purpose the strength she acquired by trade before it. But he considers that the extreme measure denoted by the announcement to which he objects is impossible, because impractical. He must, I think, be considering the matter retrospectively, and recalling to mind the huge English market for German goods. He remembers how that was obtained, and knows that human nature is too weak to fight against the impulse to buy the cheaper article, without regard to a patriotic motive. He decided then that the notice you publish cannot be maintained, and conscientiously lodges his complaint.

But, let him consider this: that Germany will commence after the war seriously handicapped. Not only will she have to overcome the nauseating feelings that decent people have for the Kultur spirit, but she will find her trade not merely interrupted but absolutely broken. She will want to advertise—no success is possible without that—and the prevention of this will make it well nigh impossible for her to compete with British firms and secure the position she had four years ago.

We have a fight before us no doubt, but success is absolutely essential. To achieve it we must discourage German trade (to prevent it, of course, would be the ideal), and we must encourage English trade to larger and consequently cheaper productions by securing it an increased market.

There is another point that has occurred to me, and, if you will permit me, here it is.

Germany must know of our feelings towards her post-war trade. Even now she will attempt, if possible, to counteract them by every underhand means in her power. To do it openly is as yet impossible, and even un-Hunnish; but how about her scheming in a manner similar to that adopted by Mr. Ives?

In saying this I merely wish to explain my point, and hasten to offer my humble apologies to the gentleman named, who, I have not the slightest doubt, has been impelled by motives the most sincere and patriotic. I am sure that if he should consider the question again he will be brought to think with me. This indeed is the sole purpose of my letter.

PHILLIP J. ADAMSON, 2nd S. Lancs. Regt.

Sir,—I should like to protest at the tone of the letter on the above subject, signed "Briton." Abuse of a person, because he holds certain views, is no argument. I do not for a moment agree with F. Jones and others who write and threaten to stop reading *The Motor Cycle* because of its attitude to German goods, for they give themselves away by their words, *i.e.*, they are threatening to boycott you just because you suggest boycotting German goods. In a word they are going to do the very thing they condemn. But abuse is not argument against them.

There is, however, another side to the question of not using German goods after the war. The German peoples will have to live after the war, as "X.Y.Z." in his reasoned letter says, and though we all hate the German methods of war, to me this boycott seems like hitting a man when he is down, and this is unsportsmanlike. If we beat the German nation, they will be the men who are down and out. Why go on kicking them then? Hundreds and thousands of the German people are just as innocent as the folk at home; they no more wanted this war than we did. Are we to go on making misery and suffering for the innocent, when all this present suffering is over?

By all means tax German goods after the war, or find some means of preventing the German nation from accumulating riches for the prosecution of a new and more terrible war. You will not, however, do it by stopping trade with the huge population of Europe. Boycott of German goods will continue the hatred, and father the determination to "have their own back" as the boys say.

We, too, have goods that the Germans want for industry and trade, and wholesale boycott of German goods seems to me to imply wholesale boycott for English goods in Europe (Central).

Let us be reasonable. Granted we win, let us remember that all ethics and morals point out most clearly the following:

When a war, for just cause and through necessity, is undertaken, it should be carried on, *not for the ruin of the nation against which we fight*, but for *securing the rights of our own nation and the Allies, and* in order to obtain *peace* and *security*. Having gained our victory, we should deal moderately and with Christian charity (are we not crying out because the Germans are violating the ethics of Christianity?) towards the conquered, and consider ourselves as a judge between the States, the one which is injured and the one which has inflicted the injury, but we should not act as avengers, but as a judge bound to preserve the *just rights* of both sides.

If we are going in for boycott for the sake of revenge, then we shall put ourselves and our cause on the wrong side, and for just this reason I very much deprecate the cry of "Boycott German goods"—in other words, Do not be sportsmen, but go on kicking the chap when he is down and out in the fight.

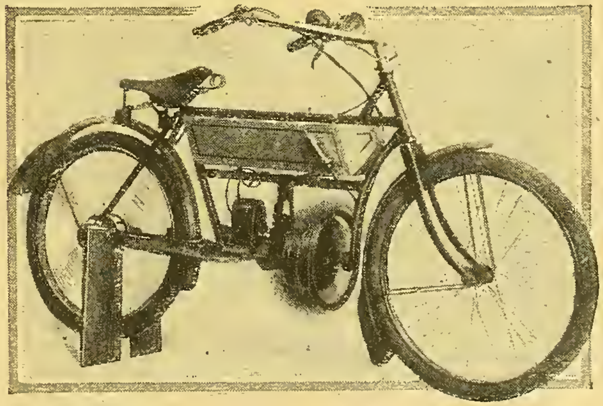
R. C. MEASURES (REV.).

ACCESSIBILITY.

Sir,—I have read the article *re* American and British motor cycles with great interest, and note one query that, I think, cannot but give some little misconception of my firm's machine.

Speaking of "really vile faults," it is asked, "Does 'Chinook' know of a big four where it is necessary to drive out the gudgeon pin, after slightly lifting the cylinder, ere the cylinder can be removed?"

I know of no other machine sold as "big four" than the Norton, and such necessity in the case of this machine certainly does not exist. In no Norton model is it necessary to disturb any part of the engine in order to remove the cylinder, except the cylinder itself. JAS. L. NORTON.



In view of the present interest in rotary engines, we illustrate a motor cycle described in August, 1912. It was built by the Gyroscopic Motor Syndicate, Ltd., and photographed whilst the engine was revolving at 4,000 r.p.m. The photograph of the machine is quite sharp, demonstrating that the engine was practically vibrationless.

"THE OLD QUESTION."

A CORRESPONDENT has been taking me to task over my remarks in a recent article showing my preference for a four-stroke, except as a short distance mount. The writer, who is a sergeant-major in the Inns of Court O.T.C., is the satisfied owner of a 2½ h.p. two-speed two-stroke Allon. It was purchased early in April of last year, and has been a source of pleasure to himself and wife ever since. He goes so far as to say that his machine is as good as any on the market and better than many. It has done a good mileage this season, and goes as valiantly as ever.

It is early days to speak of any machine's good wear or otherwise; the first season should be the most inexpensive as regards replacements and spares. Without being pessimistic, I would remind him that there are many sides of motoring, but the joys outweigh the disadvantages in most cases, otherwise fewer people would ride. His wife, too, has learned to drive the machine, and by taking turn and turn about from saddle to carrier they have during the past summer travelled long distances during week-ends and have felt little weariness after many miles. I quite agree with my correspondent's high opinion of his two-stroke, but this is not unusual behaviour for any good mount, not necessarily two-stroke or four.

I have never owned an Allon, that is one of the few makes of which I have no personal experience. Perhaps after the war I may have the pleasure of closer acquaintance, and then I hope to be able to endorse all his kind remarks, which are most complimentary to the manufacturers. Sgt.-Maj. James says: "There are no valves to grind in, no timing gear to slip, and one-third the number of parts; all is simplicity and elegance." These remarks reek somewhat of the professional salesman. Were they picked up, I wonder, at the same time as the machine? I hope I am not doing him an injustice.

The machine has been ridden through Oxfordshire and Berkshire on journeys of over a hundred miles without once needing the use of the second gear. On military business, of course——!

Running Costs.

Mrs. James on her Allon two-stroke.

His statement of mileage and cost up to the end of October last is most interesting. Very few riders have such a long purse that ways and means can be ignored. For a person whose motoring knowledge at the date of purchase was practically *nil*, they are by no means exorbitant; 1,930 miles are recorded for the season's riding at a cost of £5 19s. for fuel and slight repairs. This works out at considerably less than 1d. per mile, and under last summer's adverse conditions, but another £3 11s. 6d. has been expended for extras; that is, spares that have not yet been needed—a new belt, front and rear lamps, and licences for himself and wife. These latter, I consider, should really be placed in the running expenses, as they require renewing each year.

Having watched the operation of taking down the engine, Sgt.-Maj. James can manage to do all the decarbonising necessary, and when the Allon begins to four-stroke its cylinder is removed; a judicious cleaning repays by ease of starting and regular running. This is most creditable for one who is almost a beginner. I am always pleased to hear the views of correspondents, especially those whose enthusiasm has not been damped—or shall I say diluted?—with the weird mixtures thrust upon the long-suffering motor cyclist in place of Shell I. and mixtures, however poor they may be.

MAY WALKER.

Mr. Macpherson, replying to Sir W. Dickenson in the House last week, said: "It has been decided that, with the exception of a comparatively small number of men who will be retained to perform definite duties, such as guards, etc., no volunteers will be kept in the force after March 31st next who have not undertaken to serve until the end of the war and to perform a certain programme of training."

THE SOCIABLE SIDECAR.

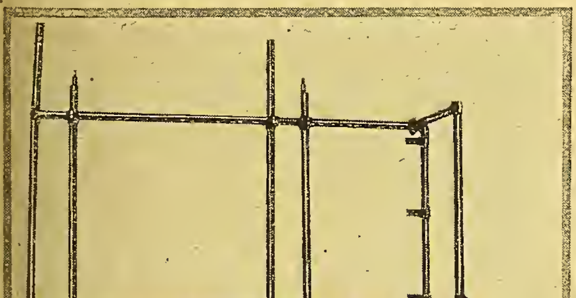
A Type of Passenger Motor Cycle which may have its Share of Admirers in the Future.

We have already referred to the possibilities and probabilities in front of the side-by-side sidecar which seats not only the passenger n the strict sense of the term, but also the driver of he machine. In a recent article on sidecars we mentioned an early machine of the type known as the H.S.M., and we have been interested to receive from the designer of this machine particulars of his latest and improved model.

The main innovation in the new model consists in the utilisation of a one-piece underslung chassis unit, and this, of course, is in itself an entirely commendable and only too uncommon a practice. It has been more than once suggested, indeed, that the sidecar and motor cycle combination of the future even when built after those lines that are at at present regarded as conventional, might advantageously be built up in one piece, in so far as frame construction alone is concerned. The disadvantages of numerous connections that may become loose are too well known by all experienced riders, and, while there is no doubt that the single unit construction has some drawbacks, there should be little room for doubt that on the whole it is far ahead of the rival system.

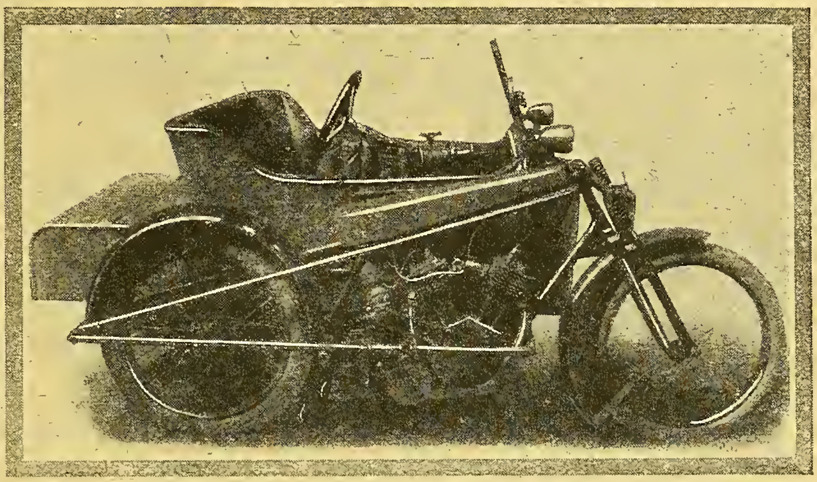
Constructional Details.

The springs are of the semi-elliptic type, the chain adjustment is by means of eccentrics, and all the wheels are detachable and fitted with internal expanding brakes. We are informed that improved shock absorbers are fitted, but are given no details as to their nature, and they are not visible in the illustrations we are able to reproduce.



The chassis of the sidecar is integral with the frame of the machine.

These illustrations make many points of the construction clear, and it will be seen that transmission is by means of countershaft and chain, the countershaft also containing, of course, a three-speed gear box (of Chater-Lea type apparently), allowing for handle starting of the engine. Naturally full provision is made for all driving control to be from the inside of the car body—and it may be incidentally noticed that this body is much more after conventional car lines than is usually the case in a vehicle of this type. The wheel steering is also claimed to be of the irreversible type, but how this very desirable feature is attained we are not told. The mudguards, as may be seen from a close inspection of the complete machine, are attached not to the body, but to the frame, so that when the body is removed the mudguards are not disturbed.

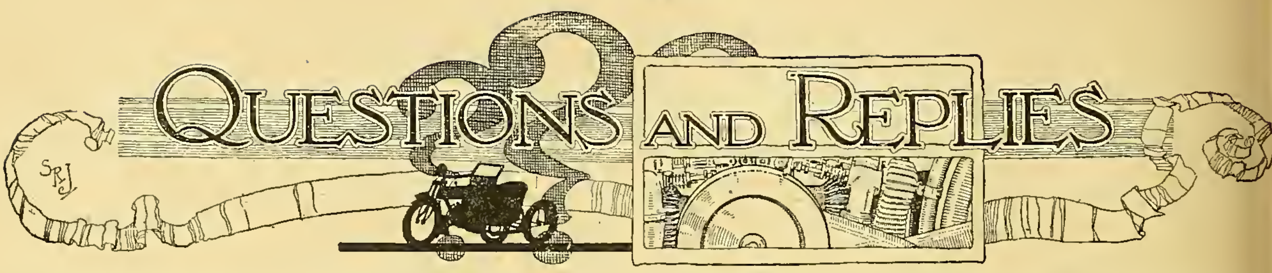


The most recent design of the H.S.M. sociable sidecar.

Future Prospects.

The name and address of the maker are F. Hellens, 151, New Cross Road, Deptford, S.E., but we may assure readers they are likely to obtain little satisfaction from writing to Mr. Hellens, as he is too busily engaged on more important work to attend to the sidecar business as he would like to, and he has had to postpone many anxious enquirers till *après la guerre*, when he hopes to market his product under the name of the Hellenson.

Two names well known to our readers appear in the list of members of the new Road Transport Board: Sir Evan D. Jones, head of the Petrol Control Department, is chairman, while one of the members is Col. H. N. Foster, Assistant Director of Supplies and Transport, War Office. Col. Foster was one of the original M.T. officers in the Army. He was a captain when the war began, is now a full colonel, and was a member of the Mechanical Transport Committee before the M.T. Section of the Army Service Corps was founded.



QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Use of Petrol for Testing.

I recently bought a second-hand motor cycle. May I legally run it on the road for testing?—S.P.

Under the Motor Spirit and Gas (Consolidation) Order, 1918, you are allowed to make a journey not exceeding twenty miles in connection with the sale of a motor car or motor cycle, provided permission is obtained from the superintendent or local chief officer of police, who will issue a permit if he thinks the case one able to justify his adopting such a course.

Intermittent Firing.

I have just overhauled my Allon two-stroke, and on trying it on the road I found it had developed a habit of intermittently back-firing through the carburetter. This occurs mostly on low gear and at slow speeds. At faster speeds the machine runs well, with only an occasional back-fire. The carburetter (Amac) is quite clean, the magneto set just to break with the piston at its highest position, and spark lever in fully retarded position.—S.A.H.

We should say that the trouble is likely to be due to the jet fitted being of incorrect size, and we should therefore recommend you to try the next size smaller, and if that does not suffice the next size larger.

Water Injection.

I notice in a recent issue a suggestion that a drop of water let into the cylinder on the suction stroke has certain advantages. What are they? Again, I fail to understand why, when a drop of water gets into the tank or carburetter, it stops the engine. Why should it do so in this case and not in the way suggested by your correspondent?—H.G.

The drop of water has some effect in aiding the explosion, owing to the fact that it is turned into steam immediately and expands. It also prevents knocking, and consequently the engine is claimed to run more sweetly. With regard to water in petrol, this has an exceedingly evil effect. Water and petrol do not mix; the water, being much heavier, consequently falls to the bottom, rolls about the tank in globules, and if it gets into the petrol pipe it drops down and accumulates at the base of the jet, preventing the flow of petrol.

Loss of Power.

I have a 1914 motor cycle fitted with a 2½ h.p. Precision engine. Lately the machine has lost a great deal of its power, and will not take a hill of any serious gradient without assistance of the pedals. The machine is only fitted with one speed. Do you think it would be any real improvement if I fitted it with a two-speed hub? The machine goes excellently on the flat, but seems to be unable now to negotiate a hill.—H.J.

Certainly with such a low-powered machine we should say that a two-speed gear of some kind would be a very valuable asset. Evidently the machine wants thoroughly overhauling—valves grinding in, worn parts replaced, etc.—and this want accounts for the loss of power.

IMPORTANT NOTICE.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

T.T. History.

I am thinking of purchasing a second-hand Matchless motor cycle. It has a 4-5 h.p. overhead valve J.A.P. twin engine, a variable gear on much the same principle as the Zenith, but operated by a lever, and it has a round tank. I am informed by the owner that this machine was ridden in the 1914 T.T. Would you please let me know (1) if a machine of this description has competed in the T.T.; (2) if so, who rode it; and (3) state where it came in? Also would you let me know (4) its probable speed when new?—P.J.H.

(1.) Yes; a machine of this description did compete in the Tourist Trophy Race, but not in 1914. It was in 1912. (2 and 3.) It was ridden by H. A. Collier, and finished third. (4.) The average speed in the race was 46.5 miles an hour, which probably means that at times the speed was well over sixty miles an hour.

Use of Fuel.

I have a little petrol, part
which I had left on my ol
licence of more than a year ag
I am engaged on aircraft worl
and have to walk three mil
very early in the morning owing
restricted train service. Should I
allowed to use up my petrol and an
other I could obtain, or paraffin,
get to and from my work? I wish
be sure, as I am not going to rene
my licence if I am not allowed to u
my machine.—H.P.

The best course for you to adopt woul
be for you to consult the police in t
district in which you do your ridin
The decisions of individual benches

fuel in a motor.

Hardening.

I intend fitting four ne
gudgeon pins in a four-cylind
F.N. (1.) What kind of ste
is best for these? (2.) In cas
hardening them, what is a goo
compound to use, the correct heat
which to keep them, and for ho
long? A few details as to cas
hardening would be acceptable.—H.L.

(1.) Gudgeon pins are usually made fro
some good quality mild case-harden
steel. (2.) Various compounds are use
depending on the plant available f
carrying out the job. To harden such
thing as a gudgeon pin satisfactorily,
should be packed in a pot with Kasen
Scintilla, or some other hardening co
pound, and heated for a period in t
furnace, after which it should
quenched in oil and then tempered. T
probability is that, if you have to
the job with the ordinary amate
appliances, you should put the finish
pin into a hearth built up of charco
and bring to a red heat with a bl
lamp, and then continually apply cryst
of ferro-prussiate of potash for so
little time, so that the ferro-prussiate g
well soaked into the metal. After t
the article is quenched dead hard a
tempered. In tempering, first of
brighten the part with emery cloth, a
then heat it till it turns a dark str
colour, and at this instant quench imme
ately in water. To make a satisfact
job of such a large part as a gudge
pin with amateur appliances is not ea
and it is doubtful whether you will eff
this unless you are experienced.

Loss of Power.

I have a 2½ h.p. two-speed two-stroke motor cycle, which ran well until a short time ago. Now it does not pull so well on hills, and when hot it loses power very quickly, even on a slight incline. The bearings are good, and also the compression shows no leakage. I shall be much obliged if you will kindly say to what you attribute the loss of power. The machine is a late 1914 model, and has had little and careful usage. The rings are not gummed or stuck in any way.—F.S.

t is rather hard to say what is the matter with the machine without actually seeing t. We should be inclined to think, how-ver, that an improvement could be effected by fitting a smaller jet. Of course, if the machine has been used for a long time, perhaps a new piston and rings are necessary.

Unequal Compression.

I have a 5 h.p. 1915 American twin, and find it very difficult to keep the compression good and approximately equal in both cylinders. When I put new rings on the pistons the compression only keeps good for 200 or 300 miles, although both cylinders get plenty of oil. There are only two rings on each piston, and the gaps are all cut the same way. If I put on rings with step-cut gaps, do you think they would hold the compression any better? How are the rods that hold the cylinder heads down removed from the crank case, so that I can get the cylinders off to fit new rings?—T.D.

A good many people have this difficulty with twin-cylinder engines. The thing to do is to find out where the leakage of compression is. It may not be at the rings at all. Step-cut rings may improve the compression, if the leak is at the rings. To the best of our recollection the rods are screwed into the crank case, but there is no necessity to disturb them, as the engine must be removed from the frame. When the nuts have been undone, first the head will come away, and then the cylinder.

Hub Gear Trouble.

I have a 4 h.p. Bradbury motor cycle fitted with an Armstrong Mark II. hub gear. Will you kindly inform me (1) how I can get the clutch to pieces, as I think it has got fixed and will not release? I cannot get the rod in the spindle to push in, and so cannot get free engine. (2.) Is this hub suitable for sidecar work with gears of 4, 5, and 7 to 1? (3.) Can I get the valve guides out of the cylinder without damaging them, and how? (4.) What is the valve and magneto timing for this machine with sidecar?—W.G.

(1.) Instructions as to taking the Armstrong gear to pieces appeared in *The Motor Cycle* of December 7th, 1917 (a copy of which issue will be sent to you post free on receipt of 3d.) If this does not give you the information required, we should recommend you to get into communication with one of the firms who advertise in *The Motor Cycle* as specialists in Armstrong gears. As regards adjusting the clutch, it is important that the operating mechanism, consisting of a bell-crank lever, should be screwed on to the spindle the correct distance, so that the push-rod lever rests upon the spindle thread within $\frac{1}{32}$in., in order to ensure the correct transmission on the push rod inside the cone spindle. (2.) The hub will do for sidecar work, but the ratios are much too high, the correct ratios being 5½, 8, and 11 to 1. (3.) If the valve guides are not cast in the cylinder (Messrs. Bradbury and Co. made, as well as this pattern, a type in which the guides were driven in), and if yours are driven in, they can be punched out with care without being damaged. (4.) The inlet opens 12°, or 1 mm. past the dead centre of the top of the stroke, and closes 33°, or 7 mm. past the bottom of the stroke. The exhaust opens 16 mm. from the bottom of the stroke and closes 1½ mm. past the top of the stroke. Set the magneto points to break with the piston on dead centre and the ignition lever two-thirds retarded.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY

During 1918 the restriction on the import of paper and paper making material is very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week.

Remagnetising Magneto Magnets.

I have a magneto which requires remagnetising. Will you kindly inform me the correct way to proceed, as I have a dynamo, accumulators, and light from town's installation?—J.F.

As you have had no experience of remagnetising magneto magnets, we should not advise you to attempt it. There is far more in the process than you appear to imagine, and we regret that a full description of the necessary apparatus would occupy more space than could conveniently be devoted to it on this page. Also the cost of the apparatus would probably considerably exceed that charged for remagnetising by a firm who make a speciality of this work. Again, a slight mistake would injure the magnets.

RECOMMENDED ROUTES.

TIDWORTH TO LEICESTER.—A.W.

Tidworth, Hungerford, Wantage, Oxford, Banbury, Southam, Rugby, Lutterworth, Leicester. Approximately 120 miles.

WIDNES TO MANSFIELD.—G.J.

Widnes, Warrington, Knutsford, Chelford, Macclesfield, Buxton, Bakewell, Chesterfield, Mansfield. The road is hilly between Buxton and Mansfield.

ENFIELD TO BOURNEMOUTH.—C.E.M.

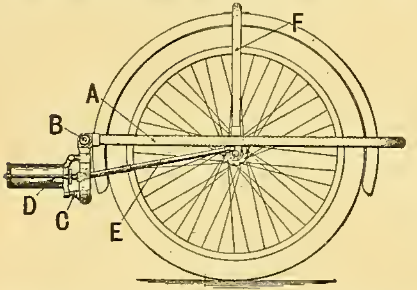
Enfield, Chase Side, Barnet, Elstree, Wealdstone, Greenford Green, Greenford, Norwood Green, Hounslow, Staines, Egham, Bagshot, Blackwater, Hartley Row, Basingstoke, Winchester, Romsey, Cadnam, Lyndhurst, Christchurch, Bournemouth. The first part of the route from Enfield to Hounslow is the road marked in blue on the R.A.C. Official Map of Recommended Routes Round London (obtainable from these offices, price 1s. 10d. post free). Return *via* Winchester, Kingsworthy, Alresford, Alton, Farnham, along the Hog's Back to Guildford, and through Chertsey to Staines. Thence as above.

French D.R.'s chatting in a tree-lined road in France. The quality of the roads leads one to surmise that the scene is far from the Front.

PATENTS by Eric W. Walford

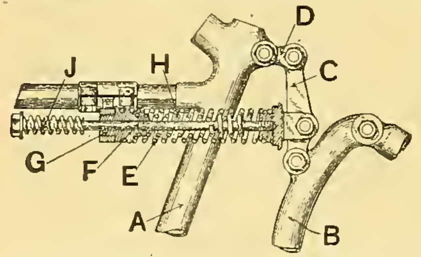
Sidecar Wheel Suspension.

The sidecar wheel is mounted in a member A, which may extend completely around the wheel, and is pivoted at B to the frame. Projecting downwards beneath the pivot B is a rigid member C, supporting a cylindrical chamber D, in which is arranged a spring device that may consist of a single spring acting in both directions, or two separate springs working oppositely. The spring system is connected to a point near the wheel spindle by a rod E, so that as the wheel rises and falls the rod E is moved, actuating the springs, and damping out the shocks. The wheel-carrying frame is further strengthened by an arched member F, which extends completely across the wheel, so that a very strong and neat construction is provided.—W. Douglas, No. 111,589.



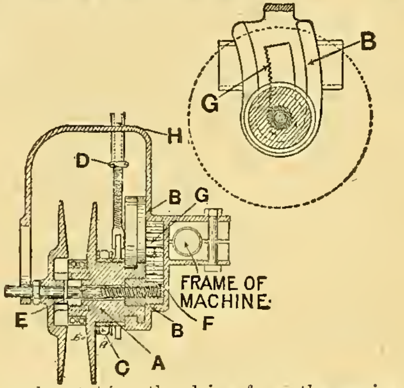
Rear Springing Mechanism.

A indicates the main frame, and B the upper portion of the rear sprung frame. The feature of the invention consists in the springing. It will be seen that this comprises a large main spring E, which is anchored at both ends so as to act both in tension and compression. Further, a rod F is connected to the link C, and passes through the abutment G carried by the main frame. Upon this rod, and inside the main spring E, is a second spring H, whilst a third spring J is threaded upon the rod in front of the abutment G. The springs H and J have some clearance at one end. Thus, for light shocks the main spring E only comes into operation, but when heavy shocks are sustained and the spring E is considerably deflected, one or other of the auxiliary springs H or J is brought into action, supplementing the spring resistance and preventing fracture. — W. Douglas, No. 110,272.



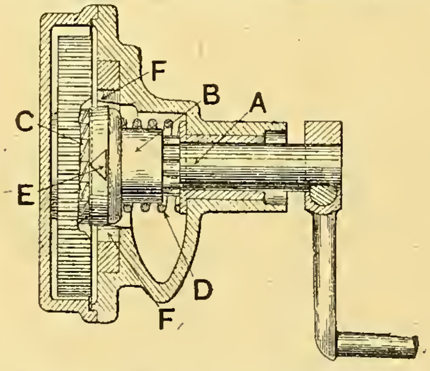
A Variable Pulley Gear.

The body of the pulley A is movable in an arc having the centre of the engine-shaft as centre and is guided by a member B forming part of the frame. The sprocket taking the drive from the engine is shown at C, and the sliding movement of the pulley is brought about by the screwed rod mechanism D, operated from a cranked handle (not shown). Passing through the pulley body is a screwed stem E, upon which threads a nut F formed with teeth which engage a rack G, so that as the pulley slides in its guides the rack actuates the nut F, causing the stem E to actuate the movable pulley flange G. Thus, the pulley adjustment and the belt tension are varied simultaneously, and the parts are so disposed that the adjustments are proportional.—A. C. Muir, No. 111,761.



An Ingenious Kick-starter.

The starter-shaft A is provided with a clutch member B, which is free to slide, but not to rotate thereon. The clutch member has ratchet teeth corresponding with similar teeth on the gear wheel C, and these teeth are caused to engage by the pressure of a spring D. In the drawing the device is shown at about half stroke in its operation. On the clutch member B is a projection having inclined faces, and corresponding faces F are provided on the casing, the inclines being such that at the end of the stroke the projection E and consequently the clutch B is caused to move back against the spring D, disengaging the ratchet teeth. The starter is drawn back to its initial position by a spring, which is not shown in the drawing, so that the projection E is engaged by one incline F, and when not in use the starter is positively held clear of the teeth carried by the gear wheel C.—Triumph Cycle Co., Ltd., and G. E. Stanley, No. 111,759.



SPARKLETS

Friction Springing for Motor Cycles.

We are informed that the spring frame design shown on page 74 (January 24th) is now fully patented for application both to motor cycles and pedal cycles.

Home Enamelling.

Those of our readers who desire to re-enamel or touch up their motor cycles should apply to Messrs. Jenson and Nicholson, Ltd., Stratford, London, E.15, the makers of Robbialac, for their latest pamphlet on this subject. This contains much useful information.

Rumours of Amalgamation.

A rumour has been widely circulated to the effect that Auto-Carriers, Ltd., is about to be amalgamated with a large firm engaged in Government contracts. We have been requested by the company to deny the statement, which is wholly unfounded, no move in the direction suggested being in contemplation.

Increase of Prices and Suspension of Models.

Owing to increased Government demands, Messrs. H. Miller and Co., Birmingham, have been compelled to suspend certain models contained in their current catalogue. Prices are also advanced in accordance with a new scale which came into force on January 14th. Enquiries are invited, and full details as to the models suspended and the new prices referred to will be supplied on application.

Goodyear Provincial Showrooms.

The Goodyear Tyre and Rubber Co. (Great Britain), Ltd., inform us that, although their provincial showrooms have been closed for the duration of the war, their premises at 3, Southgate, off King Street West, Manchester, are still open for the despatch of goods, while they still fit solid tyres there for heavy commercial vehicles for Scotland and al the North of England.

Simplicity.

The New Rover Cycle Co., Ltd., Coventry, have received an interesting letter from a captain in the Army attached to the Hythe School of Musketry. He informs the manufacturers of his machine that, having injured his leg and so having time at hi disposal, he decided to clean his machine, and without leaving his chair he was able to remove the cylinder, scrape the piston and combustion head, and replace it in an hour. "I have never bothered to do this myself before," he writes, "most machines being so inaccessible, and I think it speaks well for the design of the 1917 Rover. I have found the machine most surprisingly powerful, capable of taking a heavy passenger and sidecar anywhere." This is certainly a testimonial of which the New Rover Cycle Co. may be justly proud.

British Magnetos.

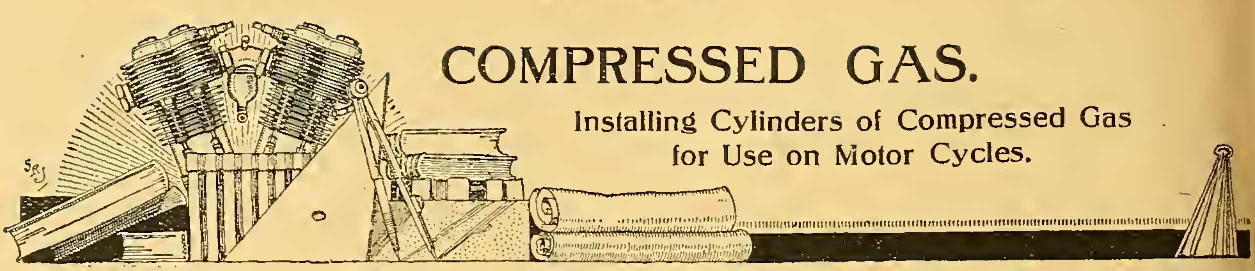
FOR many years we have urged the importance of making magnetos in Britain. This subject was first touched upon before the war, both in our pages and in those of our parent journal *The Autocar*. The dangers of allowing so important an industry to remain in foreign and possibly hostile hands was then vigorously pointed out. Naturally, in the fateful days of August, 1914, when we were faced with the very dangers we had foreseen, the magneto question became one of supreme importance, and our readers will doubtless remember that we left no stone unturned to further the object we had in view, viz., the perfecting and manufacturing of the British magneto on a really adequate basis.

Our efforts were quickly rewarded. The magneto manufacturers, instead of being numbered by ones and twos, became more numerous, and the outputs rose from tens per week to hundreds, and even thousands. Our American cousins, too, came to our assistance, but they, like ourselves, lacked the experience of the Germans. At first the instruments which we turned out could hardly be described as satisfactory. They worked, it is true: some well, others badly; but the general workmanship and finish left much to be desired. Of course, this state of things did not last long. Better plants were laid down, experience showed how defects could be remedied; better organisation led to increased output, and the British magneto became equal to anything of the kind in the world, and superior to most.

In view of these facts it will be readily understood that we were much surprised when it was stated in a recent lecture that it was probable that the British motor trade would have to return to the German-made magneto after the war, because the supply of British magnetos would be totally insufficient. In our report of this lecture we called this "An Extraordinary Statement," and, we think, with reason. There is no prospect of a shortage of British magnetos; in fact, the magneto makers are wondering whether there will be a demand for their whole output after the war, and are contemplating the necessity of turning part of their extensive plant into other channels. During the past week we have visited three of the largest magneto works in the Midlands, and what we saw in these works leaves no doubt in our mind but that the full demands of the British automobile trade will be most adequately met, and that the quality of the instruments will leave little or nothing to be desired. British magnets are far superior to the German, and consequently the British magnetos will give a much better spark at low speeds. The insulating material, too, is much better, as has been proved by the most searching tests at the National Physical Laboratory; in fact, the British instrument has nothing to fear from the most careful comparison with the product of any other country.

It has been said that we do not know what the Bosch firm will put on the market after the war. This is partly true, but we know what the firm is producing at present, for the German aeroplanes which crash in our lines constantly afford us opportunities of examining the latest Bosch practice. It is inconceivable that any but the latest and best that Germany can produce will be fitted to her fighting aeroplanes, though it is, of course, possible that further improvements may be made before the cessation of hostilities. This, however, applies to this country just as much as to Germany. The British firms have equipped large experimental workshops and research laboratories, where investigations are being constantly made with regard to further improvements, and nothing is placed on the market without thorough test.

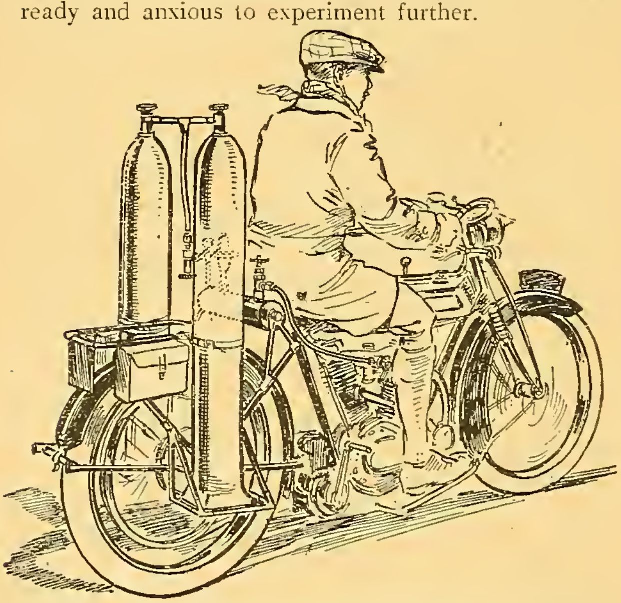
We have purposely refrained from giving figures, but our statements are based on figures that we have seen. Moreover, adequate proof has been placed before us that the British magneto is proving entirely satisfactory.



COMPRESSED GAS.

Installing Cylinders of Compressed Gas for Use on Motor Cycles.

OUR readers have for some time been familiar with the method of carrying gas in fabric containers, which are bulky, offer a large wind resistance, and hold a remarkably small amount of gas for their size. The firm of Messrs. Flugel and Co., 33a, Green Lanes, Newington Green, London, N., have for a long period studied the question of installing cylinders of compressed gas on motor cycles, and are ready and anxious to experiment further.



A suggested method of carrying gas under pressure on a motor cycle. Each cylinder weighs 47 lb. and can be made to hold ninety cubic feet of gas. The reducing valve is shown immediately behind the saddle.

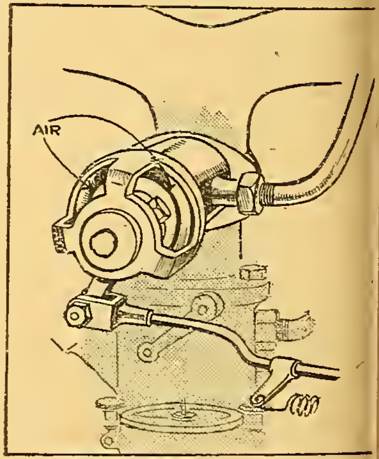
They are fortunate enough in having in stock quite a number of cylinders weighing 47 lb. each. Now, two of these would weigh 94 lb., which is a good deal lighter weight than is often transported on the rear carrier of a motor cycle, and there are few of the fair ladies one used to see riding on carriers before the war who were so slight as to weigh as little as a couple of these cylinders, which tends to show that the weight objection is not so serious as one would have been led to believe, though, of course, the total weight of the machine would be considerably increased. Probably if the weight of the reducing valve is also added to that of the two cylinders the total would be equivalent to that of an eight-stone passenger, which experience has demonstrated is not too much for the average medium-powered motor bicycle.

These cylinders are made to stand a pressure of 3,500 lb. to the square inch, which is equivalent to 235 atmospheres. Now a pressure of 125 atmospheres means the cylinder would contain 60 cubic feet; 150 atmospheres, 75 cubic feet; and 180 atmospheres 90 cubic feet. Consequently two cylinders would hold the equivalent of about threequarters of a gallon of petrol, while it is pointed out that if a sidecar were used four cylinders could be carried, which would have a total capacity of 360 cubic feet.

These cylinders are made of very light steel, and are highly suitable for the purpose, and, though the actual fitting of them to a motor bicycle has not ye been carried out, Mr. Flugel seems to think the idea is quite possible, and our artist has made a sketch showing the disposition of these and of the reducing valve—an ingenious device which reduces the norma pressure in the cylinders to atmospheric pressure, a which it is found that the gas is best introduced into the engine.

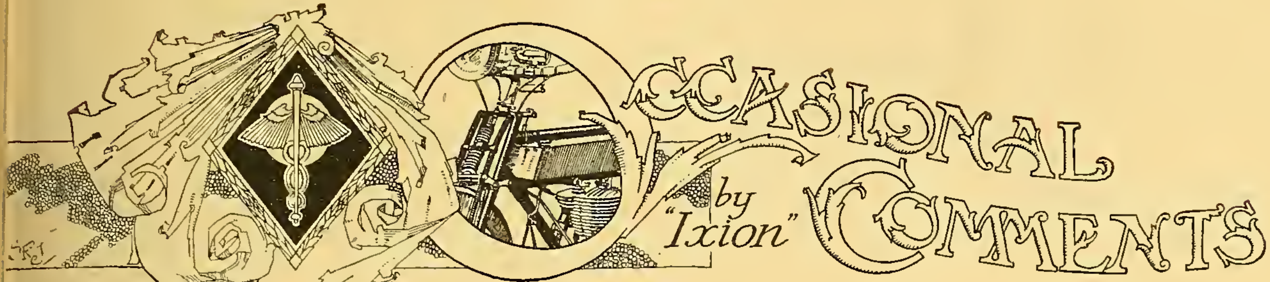
The Reducing Valve.

The reducing valve is an automatic non-return valve, which reduces the pressure by cutting off the supply as soon as a certain pressure in its chambe is reached. The gas is controlled at the entrance to the reducing valve, and again further adjustment i provided at the outlet. When the engine is once started it is a rare occurrence that either of the contro valves have to be touched, the control of the engine being carried out by a special mixing chamber which Mr. Flugel has introduced. This is a very nea device designed to clip on to the inlet pipe, and i so arranged that it in no way interferes with the working of the petrol carburetter. It consists of two valves working one in conjunction with the other, a gas valve which admits more or less gas, and an air valve which at the same time admits more or less air in the correct proportions.



Flugel gas carburetter for motor cycle engine. It may be used either with a pressure cylinder or gas bag.

When Mr. Flugel has actually fitted up a motor bicycle we shall be very much interested to hear how it behaves, and will communicate our observations to ou readers. We think that for sidecar combinations, a any rate, the installation would be a success.



OCCASIONAL COMMENTS

by "Ixion"

Extravagant Aero Engines.

SURELY "Cadet" is a little off the lines in asserting that aircraft engines are extravagant in fuel and oil, though he certainly errs in excellent company, as this fallacy is extremely prevalent nowadays. Its origin is quite obvious. Road motorists are accustomed to cover anything from 150 to 300 miles on a small tank of petrol: and the war has shown them that aeroplanes fitted with stupendous tanks have an "air duration" of no more than three hours in the case of scout machines. But have these jumpers-at-conclusions ever figured out the respective consumptions of road and air engines in relation to the power developed?

"Per B.H.P. Hour."

THE above cross-heading will mean nothing to some of our readers, but it is clear that if you are told Smith's "200 h.p." engine consumes fifteen gallons of fuel per hour, and Jones's "150 h.p." model consumes eleven gallons, you cannot work out their respective economy factors without a little mental arithmetic, especially as the "200 h.p." may actually develop no more than, say, 188 b.h.p., while the so-called "150 h.p." may give 167 b.h.p. at normal revs. Consequently, in the Services, for the purpose of comparing fuel and oil economy, the actual consumption per hour is taken, and divided by the b.h.p. at normal revs.: the result is the consumption "per b.h.p. hour," and gives a useful basis for comparison. Thus, a motor cycle engine, developing 3 h.p. at 20 m.p.h., and running at 80 m.p.g. (petrol) and 400 m.p.g. (oil), has a fuel consumption of .66 pint per b.h.p. hour, and an oil consumption of .13 pint per b.h.p. hour.

The Respective Consumptions.

THERE are, unfortunately, no standard petrol and oil consumptions for motor cycle engines. In an aeroplane the oil consumption is outside the pilot's control, and the strafe falls on the mechanics if the engine consumes too much oil. The fuel consumption, on the other hand, is more or less the pilot's responsibility, and if he handles his levers so badly that his 'bus does not register the correct economy, he either gets ticked off on his return, or empty tanks prevent his returning at all. In either case, the average consumption of fuel and oil by each engine is definitely known. I quote some approximate figures. A certain aero engine, of a type stigmatised as extravagant by "Cadet," has the following b.h.p. hour consumption figures: petrol, .54 pint; oil, .016 pint. Compared with my estimates for a motor cycle engine in the last paragraph (.66 pint petrol, and .13 pint oil), these figures are the precise reverse of extravagant.

Economy Indispensable.

A MOMENT'S thought reminds us that aircraft engines must inevitably touch the limits of economy. The designer wants a high power-to-weight ratio above all things, either in order that his machine may carry huge weights of bombs and fuel for long raids, or in order that it may outpace the enemy's fighters. The cutting down of the weight of an aeroplane to the minimum is wasted labour if unnecessary fuel and oil have to be carried.

The Contrast Pressed Home.

I DON'T want to lay any very close or heavy stress on the above b.h.p. hour comparisons, because nobody knows what the correct figures for motor cycle engines are. You buy a 3½ h.p. motor cycle, and until you have tried it out you do not know whether it will do 70 m.p.g. or 110 m.p.g. My last 2¾ h.p. did 42 m.p.g. as delivered, and over 80 m.p.g. when I had tuned it. Similarly, it is impossible to dogmatise about oil consumption, which varies between riders, between different makes of engine of the same c.c., and between sister engines of the same size and make. But it is broadly true that the carburation and lubrication of motor cycles are so crude that almost any aero engine can show better b.h.p. hour figures in both respects. This is the more astonishing when we reflect that the aero engine consumptions are registered on practically continuous full throttle work (or as nearly so as no matter), and that a motor cycle engine does most of its work on an average throttle opening of about one-third.

Extending the Comparison.

THE 10 h.p. light car, in which many of our readers are interested, perhaps affords a better basis for a comparison. Broadly speaking, the standard light car develops 10 h.p. at 20 m.p.h., and in an hour's run at legal limit uses half a gallon of petrol and a fortieth of a gallon of oil. If we based statistics on a hundred such cars in private ownerships, the consumptions would be greater and the power output less: but the above figures will serve our turn, and are in favour of the car. In other words, the b.h.p.-hour figures for a good light car in good tune are in the neighbourhood of .4 pint of petrol and .02 pint of oil. Compared with the aero engine, the petrol figures are good; but the oil figures are far worse than even the crude, oil-flinging rotary would register. Allowing for the comparatively easy duty on which the light car engine obtains its consumption, we must admit that no standard road engines can cast stones at the aircraft engines in the matter of consumption: and the many loose talkers on this subject must eat their words.

VALVE SYSTEMS ON FOUR-STROKE ENGINES.

Some Considerations of the Most Usual Types.

IN considering the types of valve systems which have been tried on motor cycle engines, one naturally considers the "mushroom" or poppet valve first. This is familiar to both old and new readers. It is practically universal on four-stroke motor cycle engines (shown in fig. 1). The reasons for this are—

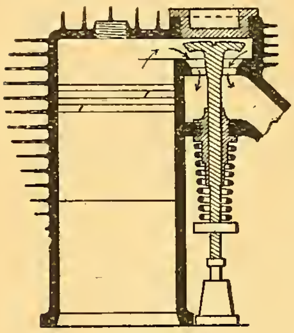


Fig. 1.—Ordinary poppet valve.

(1.) Its lightness and the fact that cylinder weight is reduced to a minimum.

(2.) It can readily be kept compression-tight.

(3.) It needs no special lubrication arrangements.

A valve system for a motor cycle engine practically stands or falls by its ability to comply with these three desiderata. Another point, however, may be mentioned, viz., the amount of work necessary for the mechanical operation of the valve. This, of course, must be kept as low as possible, but there is no example of a system which has complied with the conditions above mentioned and yet been abandoned because of difficulty of operation.

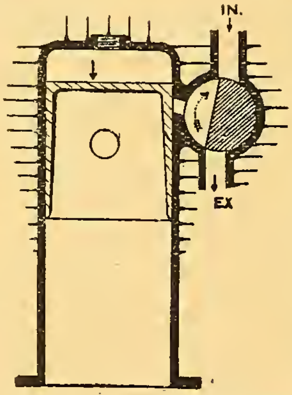

Fig. 3.—Rotary valve; commencement of suction stroke. The single valve operates both inlet and exhaust and runs at half crankshaft speed.

It will be interesting to consider the work which has to be done in operating an ordinary poppet valve, the exhaust valve only being taken into account for the moment.

Just before the exhaust valve lifts there is a pressure in the cylinder of, say, 30 to 40 lb. per square inch. This pressure, in addition to that of the valve spring, is holding the valve on its seat. Taking

Pressure gases ... = 35 lb.,
Area of valve ... = 1½ sq. in.,
Resistance of spring = 17 lb.,

then the cam operating the valve has to overcome an initial resistance of $(35 \times 1\frac{1}{2}) + 17 = 69\frac{1}{2}$ lb. This resistance drops immediately on the valve lifting; nevertheless, the considerable initial force required is often responsible for wear of the cam face. To overcome this, careful design of valve-lifting arrangement is necessary.

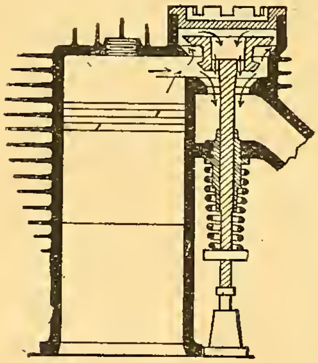

Fig. 2.—Double-seat or equilibrium valve. Lift of valve exaggerated to show action.

A method of reducing the initial force required to lift the valve is the use of a double-seat valve, a diagram of the operation of which is shown in fig. 2. By making the valve with two faces, as illustrated, the pressure of the gases in the cylinder can be practically neglected, there being as great a pressure trying to open the valve as to close it. In actual practice double-seat valves are generally made with the upper face larger than the lower in order that the valve may be lowered through the top opening on to both seats. The fact that the upper face is slightly larger will have a tendency to balance some of the resistance of the spring. This will give a very easy opening and yet retain the full strength of the spring for closing the valve.

The double-seat valve system gives better cooling, a freer exhaust, and less work done in operating the valve. It is, however, somewhat heavier than the ordinary valve. Also there is the difficulty of making the two faces compression-tight simultaneously.

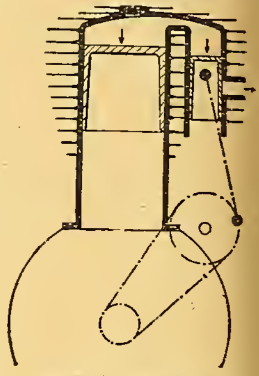

Fig. 4.—Piston valve: one valve for inlet and one for exhaust.

Sketch No. 3 shows a rotary valve arranged to operate both inlet and exhaust. This system at first sight would appear to offer great attractions. The valve can be made hollow and light, and the cylinder weight kept very low—perhaps lower than with poppet valves. Unfortunately, it is very difficult in practice to keep a valve of this description compression-tight, especially with an air-cooled engine. Also at low speeds, at any rate, this type is not as economical as the poppet valve engine.

With regard to the piston valve (fig. 4), this means a heavier cylinder and also difficulties in lubrication. There is something to be said for a small piston valve exhaust in combination with a central exhaust through the cylinder walls. In this case the piston valve would simply open for the purpose of allowing the cylinder to be properly scavenged. It would deal only with a small proportion (and this not the hottest) of the exhaust gases.

A system making use of the piston valve is the suggested Tilston four-stroke engine illustrated in *The Motor Cycle* of August 30th, 1917.

Sleeve Valve Engines.—The type of valve operation as in

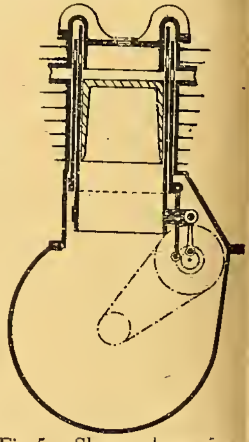

Fig. 5.—Sleeve valve engine.

lve Systems on Four-stroke Engines.—

g. 5 (but with water-cooled engine) has been satis-ctorily employed for some years. It is, of course, e Knight design used by the Daimler motor car akers. In the sketch, piston rings have not been iown. Rings are fitted between piston and inner eeve and between inner sleeve and cylinder head, ius ensuring a minimum of leakage. The sleeve valve igine can be made equally as flexible and efficient as e best poppet valve engine, and it is, of course, much ore silent in operation. Weight and cooling con-derations probably account for its non-appearance on motor cycles, but it may be added that a sleeve valve air-cooled engine was some years ago tested by the makers of a well-known sleeve valve car engine, and emerged from the most searching trials quite honourably. Yet, for some unknown reason, the type never developed, but it is probable that further experiments would render it practical—the present difficulty being, of course, the oiling of the sleeves in a way to ensure long life. These sleeves must be a reasonably close fit, and difficulty exists in retaining a sufficient film of oil under the high temperatures.

ENGRO.

A Triple-wheel Motor Cycle in Palestine.

How Two Douglas Riders solved the Problems of Sidecarring in Loose Desert Sand.

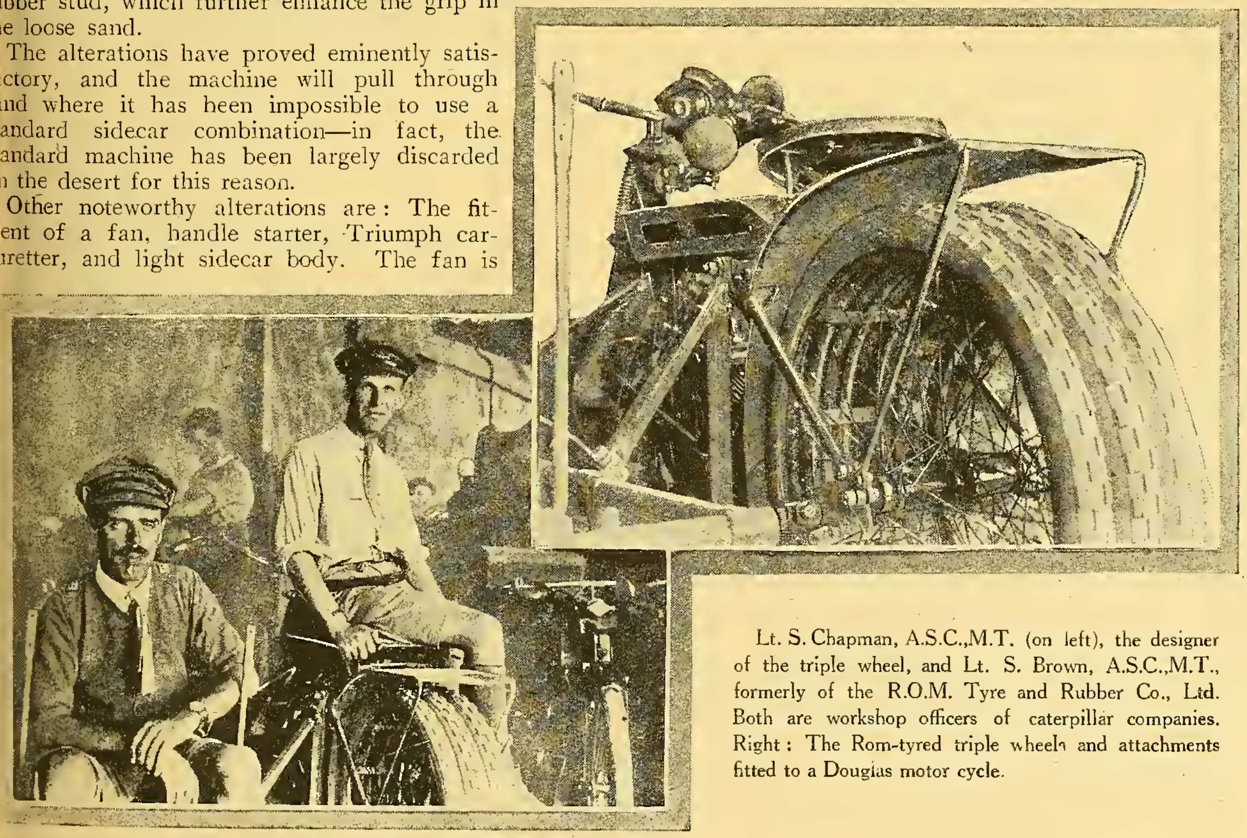
THE difficulties in using sidecar combinations on the sand at the Eastern Front will be readily appreciated, and a standard Douglas machine is been considerably altered so as to overcome these fficulties by two ingenious M.T. officers stationed in land of sand. The main difficulty encountered in ding in loose sand is, of course, the tendency of the ick wheel to bury itself, and so fail to get any driv-g grip. The two officers considered that widening e wheel would lessen this tendency, and so carried ieir theory into practice.

Briefly, two standard wheels are joined together by ie cone in the centre and a special spindle fitted. he centre rim and tyre (without spokes) is fixed the outside rims by struts, which make the whole heel as one—the back forks and stays being tered to suit. The tyres fitted are Rom special ibber stud, which further enhance the grip in e loose sand.

The alterations have proved eminently satis-ctory, and the machine will pull through und where it has been impossible to use a andard sidecar combination—in fact, the andard machine has been largely discarded the desert for this reason.

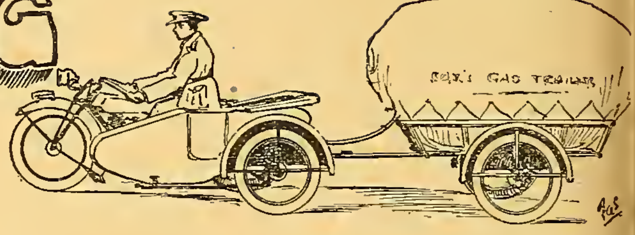
Other noteworthy alterations are: The fit-ent of a fan, handle starter, Triumph car-iretter, and light sidecar body. The fan is driven off the flywheel, and is most essential, having regard to the normally high temperatures in this climate. The foot starter as fitted by the makers is often out of action, for if the back wheel is at all buried, it cannot be used. The hand starter overcomes this difficulty, and, further, makes the engine easier to pull over. As regards the carburetter, the ingress of sand and dust is very troublesome, so a Triumph carburetter specially fitted up is used.

It may be as well to mention that Rom tyres are conspicuous on the Eastern Front on motor cycles as well as cars, one notable example of the latter being on the Armoured Car Section. This will be of interest, no doubt, to the Rom Company's trade in the Colonies, where tyres have to withstand tropical conditions.



Lt. S. Chapman, A.S.C.,M.T. (on left), the designer of the triple wheel, and Lt. S. Brown, A.S.C.,M.T., formerly of the R.O.M. Tyre and Rubber Co., Ltd. Both are workshop officers of caterpillar companies. Right: The Rom-tyred triple wheels and attachments fitted to a Douglas motor cycle.

BALLOONING

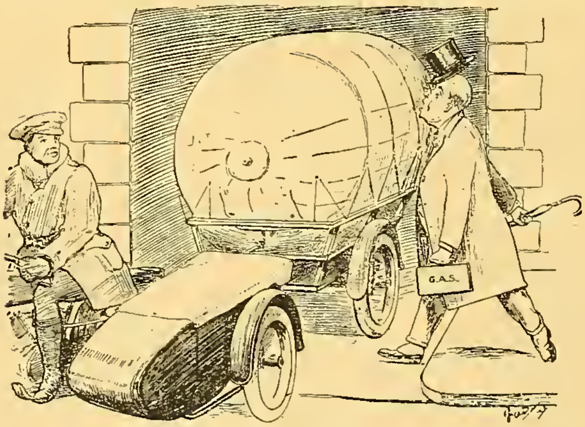


TRUE INCIDENTS—THOUGH SLIGHTLY INFLATED—DURING EXPERIENCES WITH A GAS TRAILER.

NOTHING on earth would have induced me to consent to the conspicuous task of towing a gas trailer had it not been that I could obtain my gas supply gratis from the office main. This being so, the trailer was duly installed, and amidst the jubilant cheers of street urchins I sallied forth with the balloon in tow.

All went well till I met the milkman on his evening round. The milkman's horse is one of the low-compression side by side valve variety, of Category C3, but on sighting that balloon it instantly converted itself into one of the copper-bottomed Class A fighting brand. Its first act was instantaneously and promptly to sit down in the centre of the road, ears erected, eyes bulging, bringing up the rear with a metallic clatter of empty milk cans.

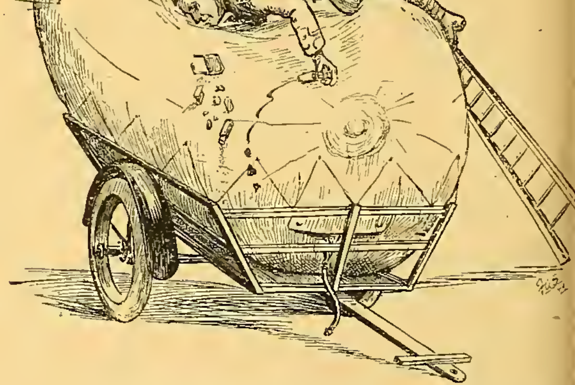
No one was more surprised than the milkman. Had his steed dropped dead and rolled back downwards with legs aspiring stiffly skywards, he would have taken it as more or less within the normal order of things, and proceeded to become used to it; now his surprise was one of paralytic helplessness. Next the horse stood straight on end, still staring with its ears, and proceeded to walk round on its hind legs in a narrow circle, till it faced in the opposite direction, whereupon the whole shoot literally slithered into a farmyard. When next day I asked the milkman if any damage was done, he replied, "Not much, sir. Only trapped his tail a bit when he sat down so sudden!" The same old horse passes me to-day with only a snort of contempt.



"Then proceeded to walk slick into the trailer."

A Collision in the Dark.

One recent dark night I emerged with the outfit from a side passage which leads into a main thoroughfare, holding up a pedestrian who was in the act of crossing the pavement at the passage head. Th pedestrian was of the prosperous commercial travell type, and, knowing that the trailer in the gloo behind was invisible, I shouted in passing, "Trail behind," to which he replied, "Same to you"- evidently thinking I was wishing him a merry Chri mas. Then having duly seen the sidecar pass, proceeded to walk slick into the trailer, his attitu being that of a man who treads on the teeth of hay rake, and is reminded of his error by the spee erection of the shaft. When last I saw him he w striking matches and groping about the pavement.



"The beastly ladder slipped, and I fell on top of the bally balloon."

On the following day we had a slight argument w a railway dray that we met in a narrow passage. T drayman shouted that all was clear, but, unfortunate he took only the trailer wheels into account, omitti to notice that the superstructure overhung somewh The result was that a corner of the trailer rail collid with a box poised perilously on the edge of the dr and from the crash that followed we judged that box was full of jam jars.

Examining the trailer on reaching home, I w surprised to find a pair of gold spectacles hook up in the gasbag, while just below was a narr jagged hole! Will the owner of the spectacles ple apply—though I would inform him that he has, spite of a warning, and probably with malice afo thought, bitten a hole clean through my gasbag! (these anti-motorists!

Somewhat Inflated.

There was once a man who made a bassinette [think our contributor means a 'cello, but has beco

Originality of Design

speaks in every line of the A.J.S., and because of what this betokens for superior service, prospective after-war buyers are everywhere increasingly deciding in its favour.

Correctly embodying every point essential for supremely-easy control, unfailing power, all-weather protection and perfect reliability — the A.J.S. forcibly evidences the richest results of thought, experience, and mechanical ingenuity. Its many original design-features include:

Scientifically built straight tube frame. Powerful, silent and vibrationless A.J.S. engine. All-enclosed weatherproof chain transmission. Kick-starter with enclosed mechanism. Special three-speed countershaft gear. Patent gate change. Handlebar-controlled perfect multiple plate clutch. Forced lubrication direct to main bearings and big-ends. Internal expanding rear drum brake. Interchangeable detachable wheels. Amply protective mudguards, etc.

Note a few details and prices of Model D: 6 h.p. Twin, 750 c.c., 3.speed, **£84** Coachbuilt Sidecar to suit, **£18 : 18.** Prices subject to 7½% advance. Hood, Windscreen, and Spare Wheel extra.

"Ask the man who owns one"

Ballooning.—

confused with bassoon.—ED.], and having completed his task discovered that he had left the glue pot inside. The following incident reminds me of that man.

We had left the trailer in a warehouse to fill slowly from the main, surrounded by large piles of crates and such like dunnage. Returning forty minutes later we were surprised to find the place in darkness, nor did manipulation of the switch cast any light upon the mystery. After careful search we eventually discovered the electric light bulb securely jammed between the fully inflated balloon and the side of a crate. Having set this matter right, we next attempted to extract the trailer, but only to find that, in its fully inflated condition, it could not be withdrawn from the building. It looked, at first, as though we should have to pull down an arch that propped up the three storeys above, but the warehouseman, being a gentleman of resource, suggested that we connect the balloon to the pipe again, then all sit on it to squash some of the gas back into the main. While we were discussing this sociable little scheme, however, the bag proceeded to flatten itself of its own free will, by breathing noxious odours through its pores, in that little way it has, and at the end of ten minutes, by means of judicious coaxing, prodding, and pushing with a plank, used as a shoe horn, we got it out of the place.

"We heard a sort of dull 'whoff.'"

But the gasbag met a sad end. One recent frosty morning my brother's son and heir espied a sparrow perched on top of it, shot at it with his air gun, and drilled two neat little holes clean through the top of the balloon fully a yard from the sparrow. I borrowed a ladder from the vicar, and got busy with a tyre repair outfit, but the beastly patches would not stick. It was like hammering a tack into a blancmange, and when I became irritable and tried to lean on the patches, the beastly ladder slipped, and I fell on top of the bally balloon. This burst it in another place, with the result that it was leaking worse than ever when that evening cook went into the outhouse with a candle to look for a carrot. We heard a sort of dull "whoff," the house shook slightly, and the housemaid, who was finishing up the bottled peas in the kitchen, cut her mouth. Then she ran into the sitting room where Arabella and I were reading.

"O! Mum," she gasped, "Cook's gone!"

The kitten shot up the curtain and growled.

"Where?" I queried, a shade incredulously.

The girl pointed dramatically to the skies. As she did so something fell with a soft thud on the gravel path without. I peered through the window—it was one of cook's felt slippers! We looked at each other doubtfully, then Arabella and I fell on each other's necks and shed copious tears. "The end of the gasbag!" we gasped hysterically.

H.M.B.

Something fell on the gravel.

LUBRICATION.

"CHINOOK'S" recent article on lubrication proves that satisfactory lubrication depends as much on the brains of the driver as on any mechanical or hand pump lubrication system. And so it does with all engines, petrol-driven or otherwise. In saying this, I must assume that the driver selects the oil and is responsible for the necessary lubricator adjustments. Any ordinary intelligence can ascertain with practice on a motor cycle how much oil his engine needs under all the conditions to which it is subjected; and he can easily feed it satisfactorily with a hand pump type of lubricator.

If he always has the Right Oil.

But every ordinary motor cyclist cannot be expected to understand the chemical composition of oils, and it is the engine designer's or producer's duty to specify the oil required. Practically all gas engine makers specify the oil that should be used in the cylinders of their engines.

I do not suggest that motor cycle designers should sell oil, but they are the men who should know best what their particular engines require, and they should at least specify the flash point, the specific gravity and viscosity. With these three points correct it would be impossible, as "Chinook" says, to get the oil in one's engine to a "viscosity akin to paraffin," no matter how overheated. The "drying up," as referred to by "Chinook," is by no means due to overheated oil, but to overheated and distorted metal due to over-driving. As proof, stand a minute with a draught of air on the cylinder, and you can restart in less time than it takes for oil to cool.

It is a common error to speak of the oil in the crank case as having a cooling effect in the sense of lowering the heat caused by the explosions. The only way worth taking into account in which heat is reduced by the oil is in its reduction of friction. If larger sumps and fins on crank case would reduce explosion-generated heat it would thereby enable a lighter oil to be used and so reduce friction, and to that extent be a good thing. But it seems of more importance to improve the cooling of the cylinder head where the heat is generated.

ILIFFE & SONS LTD.

THE A.A. AND THE UNITED COUNCIL.

The Secretary of the Automobile Association gives Reasons for Non-support.

We have several times recently dealt with the new United Council of Motoring Organisations, and we have expressed it as our opinion that such a United Council would be a good thing, and one that should receive the whole-hearted support of all motorists. There has, however, as we have already hinted, been a slight obstacle to the successful establishment of this Council, because one of our most wealthy and prominent existing organisations has refused to throw in its lot with its contemporaries. This body is the Automobile Association and Motor Union, and we are very pleased to be able to publish the following apologia from the A.A. as to its attitude on the matter, and as to its reasons for standing out. Comment on our part at the present time, perhaps, would be rather premature, so we prefer to hold over our own opinions on the matter, but in the meantime we shall be very pleased to hear those of our readers. The announcement reads as follows:

"On the 16th October last, the A.A. was invited to form part of a suggested United Council of Motor Users, Producers, and Distributers. An official copy of the minutes of a meeting convened by Mr. E. Manville and Mr. E. Powell, and held on that date, accompanied the invitation, to which, as secretary, I replied to the following effect, viz.:

> "'The committee are in entire sympathy with the suggestion of united action by all bodies concerned on matters pertaining to the production, distribution, and use of motor vehicles which may be affected by legislative or other proposals. They consider, however, that these questions can best be dealt with at conferences of the bodies concerned, to be held from time to time as occasion may arise.
>
> "'This Association was formed for the benefit of motorists and motoring generally, and to this end the committee feel that they cannot pledge themselves to support the policy of any trade body or bodies whose interests may conceivably clash with those of the private motorist; in the protection of those interests the committee prefer to remain entirely free.'

"The Automobile Association and Motor Union came into being to protect the reasonable from the unreasonable, and the measure of its development evidences the strength of that protection.

"The A.A. welcomes the co-operation of kindred bodies wherever and whenever the interests of the reasonable motorist are concerned. It is because the committee do not think that the proposed new Council can operate in the best interests of reasonable motorists that they have declined to support the scheme.

"Furthermore, the committee refuse absolutely to be fettered by enlistment in a combine, especially one whose constitution is based upon principles such as those disclosed in Paragraph III. of the resolutions unanimously adopted at the first meeting. That paragraph, part of an official copy of minutes already referred to, reads as follow:

> "'III. In respect of legislation, kindred matters and technical questions in relation thereto, to use its influence to discourage any organisation represented upon the Council from acting in a manner calculated to impede the policy or to injure the interests of any other organisation so represented, and to encourage united action and mutual support between all these organisations.'

"I invite careful attention to this paragraph—particularly to that part which aims to 'discourage any organisation represented on the Council from acting in a manner calculated to impede the policy or to injure the interests of,' *not* the general good of motoring, but '*any other organisation so represented.*' Without questioning the sincerity of those who drafted this significant clause, there must be considered with the clause the list of constituent bodies whose respective representatives unanimously passed the clause, and who, doubtless, will form the suggested Council:

> "Royal Automobile Club.
> "Roads Improvement Association.
> "Auto Cycle Union.
> "Royal Scottish Automobile Club.
> "Cycle and Motor Cycle Manufacturers' and Traders' Union.
> "Institution of Automobile Engineers.
> "Commercial Motor Users' Association.
> "Motor Trade Association.
> "Commercial Vehicle Manufacturing Interests in the Society of Motor Manufacturers and Traders and the Association of British Motor and Allied Manufacturers.

"Can it be possibly argued, except in a minute percentage of cases, that the interests of those bodies can be other than conflicting?

"Take the all-important matter of good roads. Who wants good roads? The motor user.

"Who pays most for them? The motor user.

"What does the greatest damage to roads? Heavy motor traffic and steam tractors, the users of which do not pay for them.

"Are the interests of Motor Users, members of the A.A., to be prejudiced because the hands of its executive are tied, as they would be, by a majority vote of the suggested Council to 'discourage action calculated to impede the policy or injure the interests' *not* of the general body of motoring, but 'of any other organisation represented on' that Council.

"Take the matter of motor fuel. Is it not the fact that the already exorbitant price of petrol has been advanced by the enforcement (upon all members of one of the bodies constituting the proposed Council) of a compulsory and excessive profit of 15% on the retail price of motor spirit? Compare this with the A.A.'s attitude when, several years since, it acquiesced in the middleman's 3d. per gallon as a reasonable working profit.

"Are the petrol monopolists likely to sympathise with motor users on these vitally-important matters? Is it 'business' for them to do so?

"The A.A. as trustee of the *user* is bound to regard Clause III., prescribing discouragement and restraint, etc., with far graver misgiving than evidently did the gentlemen who drafted it.

"They may *think* it is all right, but in deciding resolutely not to be allied with any trade body or bodies whose interests may clash with those of the motor user, my committee know that they are correctly interpreting the wishes of our members and of all reasonable motorists.

"Stenson Cooke, Secretary,
"The Automobile Association and Motor Union."

1913 B.S.A. HANDBOOK.

STAFF-SGT. D. GORDON, Staff-Sergeants' Mess, School of Musketry, Strensall, Yorks., will be glad if any reader will let him have a copy of the 1913 B.S.A. Handbook.

* * *

PROMOTION.

WE note with pleasure that Temp. Lt. S. A. Rowlandson, A.S.C., has been promoted Acting Capt. Capt. Rowlandson was the skilful pilot of a Rudge motor bicycle before the war, and represented the Manufacturers' Union at the inspection of the last Auto Cycle Union Six Days Trials course. He is an exceedingly popular man, and is known not only for his prowess on a motor cycle, but for his remarkable skill in entertaining, as he is a talented musician and an excellent *raconteur*.

* * *

A MAN OF MANY DECORATIONS.

BESIDES a charge of unlawfully wearing the uniform of an Army lieutenant, Leon Beavis, a Canadian sergeant, was accused at Bow Street Police Court, London, of using the following military decorations to which he was not entitled: The Victoria Cross, Distinguished Conduct Medal, the two South African medals, Mons Star, and ribbon of the French Legion of Honour. According to the police, accused had been posing as a wounded officer, and had in his possession some wooden splints, which he occasionally wore on his left leg to lend support to his story that he had lost the use of his limb. He also wore a shade over his eyes, saying, "That's what the war has cost me." Sentence of six months' hard labour was passed.

TWICE-WOUNDED MEN AND HOME SERVICE.

MR. MACPHERSON announced in the House of Commons that it had been decided that men who had served abroad since the beginning of the war, and who had been wounded two or more times, were to be transferred to home service. Instructions to this effect would shortly be issued.

* * *

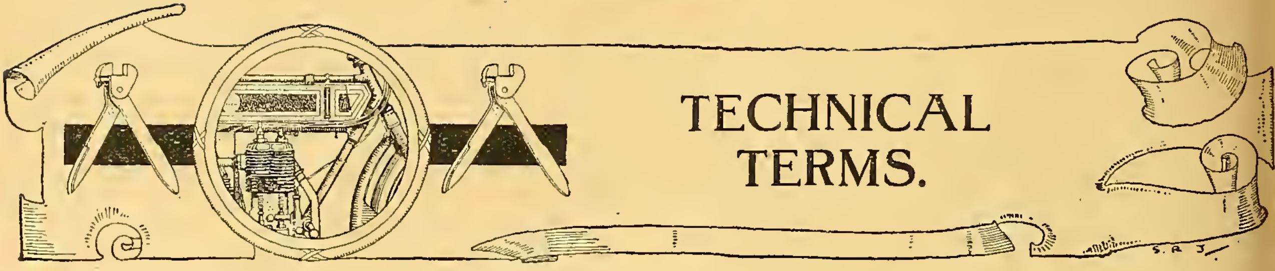
ARIEL MOTOR CYCLE EXPONENT WINS THE MILITARY MEDAL.

ANOTHER motor cyclist to win the Military Medal is Pte. Wilfred Morris, formerly a member of the staff of Messrs. Ariel Works, Ltd.

The Military Medal was conferred upon Pte. Morris for bringing in a motor lorry from the first and second line trenches during important military operations on the British front in France after previous attempts had proved unsuccessful.

Pte. Wilfred Morris.

He joined the forces in 1915, being previously engaged in assisting the Ariel Co.'s Scottish representative in his motor cycle business, and was an enthusiastic competition rider, who won many gold medals in 1914.



TECHNICAL TERMS.

SOME REMARKS ON VARIOUS TERMS USED, AND OFTEN WRONGLY USED, BY MOTOR CYCLISTS.

The meaning of certain technical terms is far from being always correctly understood, and the following series of articles by "Rama" is intended to elucidate in simple language their individual meaning. It is assumed throughout the series that the reader is acquainted with the working of the motor cycle. Discussion on any interpretation of these terms which may be at variance with the usual ideas of our readers will be welcomed.

THEY made up just such a crowd as, at the present time, even more than normally, is the motorists' main delight. Denied the open road we can do little more than talk of the times that have been and that are to be, and discuss those present developments that we hope will make the times to be even more enjoyable than those that have been. Some half-dozen other men—an R.E. Signals and a couple of R.F.C. officers in company with the works managers of a carburetter and a motor cycle firm—were so chatting, and from a relation of experiences the conversation turned to a discussion on more or less technical terms.

What really set the ball rolling was a remark by the Sapper: "I remember a ''bus' I owned in 1913 was a most extraordinary affair. Its compression was perfect, but its fuel consumption was enormous and 'speed' was Dutch to it. I always thought that good compression meant high speed and all the other ideals a motor cycle should possess."

"As a matter of fact," said Works Manager No. 1, "I think you are perhaps confusing good compression and a high compression—a very frequent error.

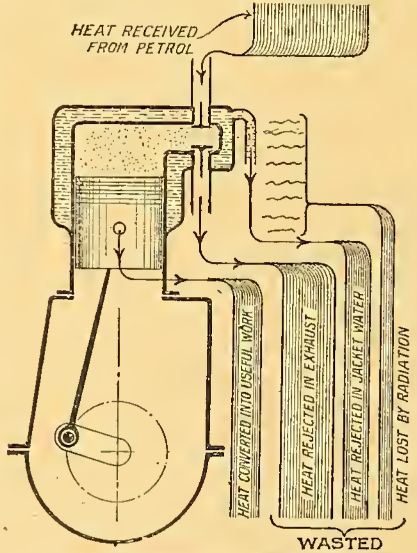
When the Sapper confessed that his ideas were a bit hazy on the subject the Works Manager enlightened him, and the conversation then ran on along similar lines. I shall simply attempt to reproduce a few of the definitions and theories put forward without attempting to chain them down to their original sponsors.

Compression Ratio.

For instance, this question of compression and "compression ratio" contains the germs of many a fruitful discussion. To give us some sort of a definite basis on which to work, let us take it as read that the petrol engine is an engine from which work is obtained by the conversion of the heat provided by the fuel into energy given out at the crankshaft.

Thermal Efficiency.

The value of a fuel is indeed measured by the number of heat units that it contains, the most commonly used unit being the British thermal unit—written B.Th.U. One B.Th.U. is the amount of heat required to raise 1 lb. of water from 59° to 60° F. (at sea level), and petrol contains about 20,000 B.Th.U. per lb., so that 1 lb. of petrol should be able to raise 20,000 lb. water from 59° to 60° F., provided none of the units was lost in the process—as a matter of fact, a feat impossible of achievement.



HEAT RECEIVED FROM PETROL
HEAT CONVERTED INTO USEFUL WORK
HEAT REJECTED IN EXHAUST
HEAT REJECTED IN JACKET WATER
HEAT LOST BY RADIATION
WASTED

Diagram illustrating the term, "Thermal efficiency." The width of the stream is in each case proportional to the amount of heat it represents, and it will be seen that the amount converted into useful work is only small compared with the amount supplied to the engine. Although this diagram represents a water-cooled engine, it is essentially correct for an air-cooled engine also, the heat rejected in jacket water being added to that lost by radiation.

Now these heat units have a mechanical equivalent—that is to say, they may be converted into work, and approximately 42 B.Th.U. should give out 1 h.p. for the space of a minute if there is no waste in the conversion.

The ratio of the heat in the fuel to that actually obtained as power at the crankshaft is known as the brake thermal efficiency of the engine. In other words, this may be expressed:

$$\frac{\text{Power given out}}{\text{Heat given in}} = \text{Brake thermal efficiency.}$$

If we feed fuel containing 42 B.Th.U. into an engine and ge from that engine 1 h.p. for a minute, the engine would be said to have a "brake thermal efficiency" of 100%, because the transference from heat or thermal to mechanica value has taken place without any loss. In practice the highest therma efficiency ever attained is abou 35%, so that two-thirds of the energy contained in the fuel i *wasted!*

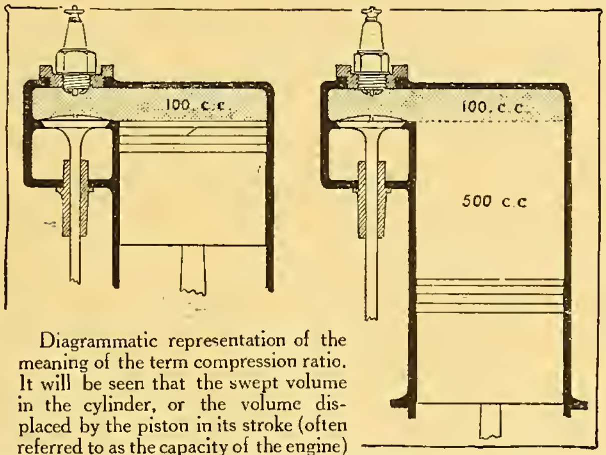
Having formed a clear idea as to the meaning of thermal efficiency we may return to a discussion o

Technical Terms.—

Compression: What it Is, and What it Does.

Before being exploded, the gas is compressed in the cylinder. Now if the cylinder allows of any leakage, either through a badly-fitting piston, faulty valves, or leakage round the caps, etc., when the explosion occurs some of its energy finds an outlet through these leaks, and consequently the whole force of the explosion is not exerted on the piston. Under these circumstances an engine is said to have poor compression, and it may in many cases be "turned over compression" by hand with little difficulty. On the other hand, if no such leaks are present the compression is good, and the whole force of the explosion is exerted on the piston.

There is, however, an entirely different aspect of the case that now needs consideration. Take two engines of the same capacity (say 500 c.c.) and with equally good compression—*i.e.*, with perfectly fitting rings and valves and no other sources of leak. Because the engines are of the same "capacity," it does not follow that the spaces above the pistons when these are at "top dead centre" are the same, and we will suppose that in one case the space is 100 c.c., while in the other it is 125 c.c. At the end of every exhaust stroke this space will be filled with gas remaining at atmospheric pressure (approximately).



Diagrammatic representation of the meaning of the term compression ratio. It will be seen that the swept volume in the cylinder, or the volume displaced by the piston in its stroke (often referred to as the capacity of the engine) is 500 c.c., while the combustion space is 100 c.c. Thus 600 c.c. is the total volume in the cylinder when the piston is at the bottom of its stroke, and when the piston is at the top of its stroke this volume is reduced to 100 c.c. The compression ratio of this engine would thus be described as six to one.

Now both engines on suction stroke take in (theoretically) 500 c.c. of mixture. This 500 c.c. has added to it in one case 100 c.c. of remaining gas, and in the other 125 c.c.; consequently in one engine 600 c.c. of gas is compressed into a space of 100 c.c., while in the other 625 c.c. is compressed into a space of 125 c.c. In other words, in the first case it is compressed to within one-sixth of its original volume, while in the other it is compressed to within one-fifth.

Compression Ratio.

These two fractions are known as the "compression ratio" of the engine, that of the first being expressed as six to one and that of the second as five to one.

An engine with a high compression ratio is colloquially spoken of as a high compression engine—any ratio above about 4½ to 1 being conventionally regarded as "high."

From this it will be seen that the fact that an engine has a low compression ratio does not necessarily signify that it may be turned easily over compression, for in many touring engines the compression ratio is low to ensure cool running and steady pulling at low speeds, but the compression itself needs to be just as free from leaks as in the case of a high compression engine. Although a low compression ratio does not necessarily mean that an engine may be turned easily over compression, it is generally the case that an engine with a *high* compression ratio is *difficult* to swing. A little thought should make the reason clear.

The Effect of a High Compression Ratio.

Now the greater the extent to which the charge is compressed, the more powerful is the ensuing explosion, and consequently the higher the compression ratio in an engine the more power will be obtained from the explosion—in other words, the greater its thermal efficiency. Unfortunately, however, the compression ratio cannot be indefinitely raised, and so thermal efficiency indefinitely increased, because compressing a gas also heats it, and if a petrol vapour and air mixture be *rapidly* compressed to within less than about one-sixth of its normal volume, it explodes spontaneously—as was described in an article on "Spontaneous Ignition" in *The Motor Cycle* on December 13th last. Consequently, compression ratio cannot be indefinitely raised, and the following extract from a recent book on "Aero Engines," by G. A. Burls, concisely expresses another argument against unrestrained raising of the compression ratio:

"Though increased thermal efficiency should accompany increased compression, it is often found with actual engines that increasing the compression results in little or no increase of efficiency, and indeed the thermal efficiency may even show a *diminution* with increased compression. This is due to a source of loss of which the above theory takes no cognisance, namely, the large loss of heat to the walls of the combustion chamber and piston crown at and near the maximum explosion temperature. This loss is greater as the surface exposed is greater relatively to the volume of hot gases enclosed; when compression is increased by diminishing this volume the ratio of surface to volume, and hence the heat loss, increases. This increase in any case must reduce any gain in thermal efficiency arising from the increased compression, and may even, as above remarked, more than nullify it. To realise the thermodynamic advantage of increased compression, this should be effected by increasing the stroke, leaving the combustion chamber unchanged in form and size.

"Due to this cooling loss, there is for each type of actual engine a compression ratio of maximum practical thermal efficiency, which is determined by experience; for petrol engines of normal four-stroke type the value is probably of the order of about 4.5."

All things change, however, and as a result of recent work on aeroplane engines compression ratios of well over 6 to 1 are now often employed. Three years ago this would have been actually impossible.

Y.M.C.A. Hut.

Mr. William Douglas, of Messrs. Douglas Bros., Kingswood, has promised to defray the expenses of one Y.M.C.A. hut, at a cost of £750.

Driving Licences in France.

The increase in the application for driving licences in France has more than doubled since 1914. In that year 11,340 were granted, and in 1917 over 24,000.

Mails to Japan.

In a letter received from a reader in Japan, the writer says that not one copy of *The Motor Cycle* which has been mailed *viâ* America has failed to reach him since the outbreak of war.

Oil from Coal Waste.

Proposals for establishing a new British oil industry by the distillation of waste material from coal mines were made at a meeting of the Institution of Petroleum Technologists in London.

The South African Motor Cyclists' Corps.

We recently had some news of the work being performed by this corps in the rounding up of the straggling Huns in "German South East." The corps is now appealing in the South African papers for further recruits.

Work of the National Physical Laboratory.

Sir R. Glazebrook, the Director of the National Physical Laboratory at Bushey, states that during the period of the war they have tested half a million gauges for munitions. Nearly all the lighter alloys used in the production of our aircraft are the outcome of research at Bushey House. In the tank, which was 200ft. long, they had at one time forty or fifty models of warships, destroyers, and great merchant ships, and, following experiments, they were enabled to show how the requisite horse-power could be secured at a saving of 10%, and in some cases 15%, of fuel.

Aeroplane Models.

The National Physical Laboratory has a special department for ascertaining the effect of wind on aeroplanes. Models are placed in a space, and air forced in up to 60 m.p.h. The staff has been increased to 500, 200 of whom are women.

New Department of Overseas Trade.

We have already referred to the new Department of Overseas Trade, which has been set up under the joint administration of the Board of Trade and Foreign Office.

Duty of Attaches.

The duty of *attachés* of this new body—who will be recruited from the best members of the Consular Service—will be to collect information, and give a real economic survey of the countries where Overseas trade is to be fostered.

Traders' Risks.

Dr. Addison, Minister of Reconstruction, has appointed a "Committee on Financial Risks" to go into the question of traders' after-war risks. The belief that with the coming of peace there will be a fall in prices, involving a loss on materials bought at the present high level, is causing a reluctance on the part of manufacturers and traders to acquire materials for the resumption of peace time production on a full scale.

Americans in Paris.

A member of our staff who was recently in Paris expresses himself as very agreeably impressed by the many American soldiers he met there. Most of them proved on acquaintance to be very fine fellows, both physically and intellectually, and though for the most part fresh from school or college, there was little in their manner or appearance to convey any impression of extreme youth—big, serious fellows, fully realising the magnitude of what lay ahead.

Special Features.

THE FOUR-CYLINDER OF YESTERDAY AND TO-MORROW.

TECHNICAL TERMS. COMPRESSED GAS

South African Motor Track.

South Africa wants a Brooklands on the Rand, but at a recent meeting convened to consider the proposal support was very scanty, and the main asset—funds—appeared to be lacking.

Queer Name for a House.

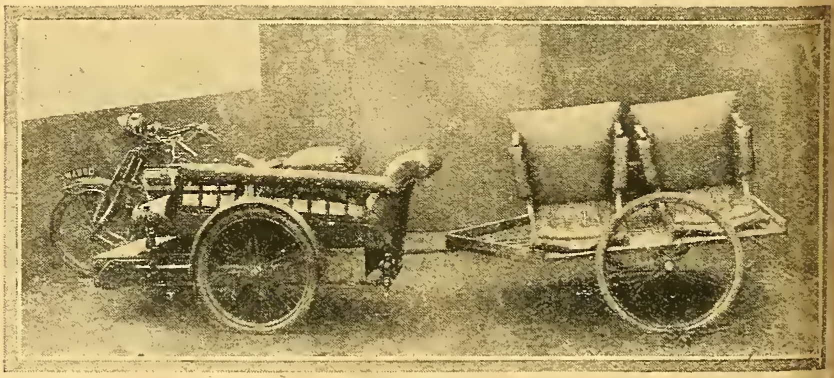
There is—or was—in Coventry a house named DU 1597, after what was, presumably, the number of the resident's car! (The actual number, by the way, we have of course, altered.)

Nerve-strained Soldiers.

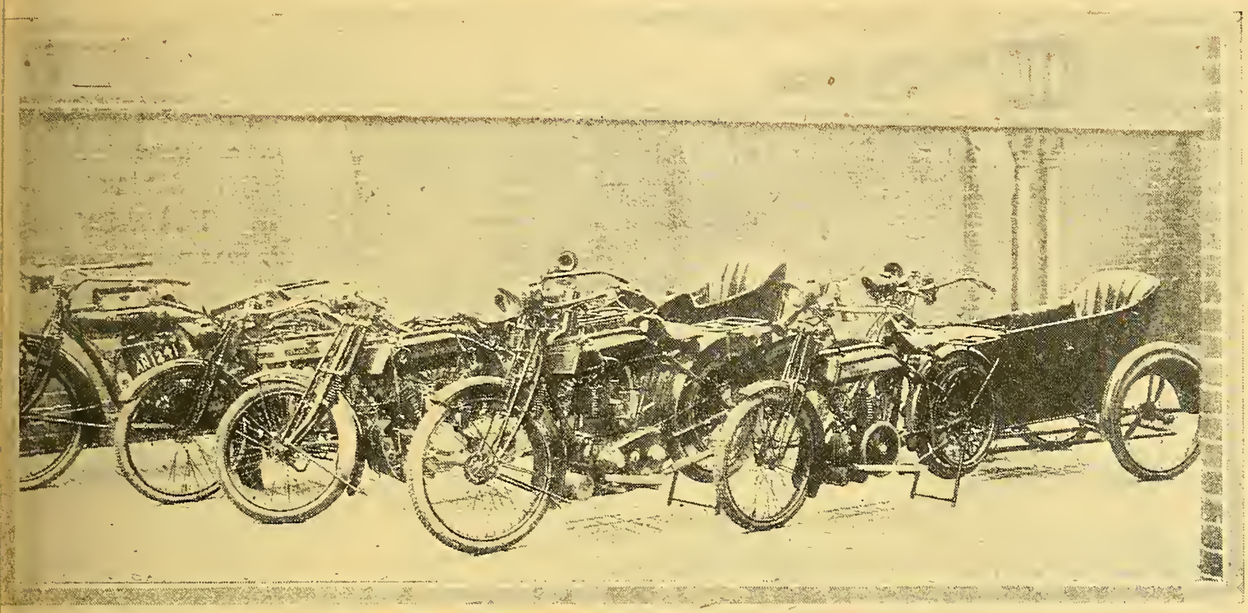
Mr. Macpherson states that eight institutions for the care of nerve-strained soldiers have been organised, and four are in course of establishment. Medical officers are being specially trained for the treatment of the patients.

War Photographs in Colour.

The first exhibition of British war photographs in colour was opened on Monday last at the Grafton Galleries London. It is a record of British operations on all fronts and in every phase of warfare. The wonderful photograph of the march through the blinding sands of an Egyptian desert is prominently hung. Soldiers who have recently been hanging the photographs have found among them pictures of themselves in battle.



An A.J.S. and sidecarrier used by Mr. Wilfred Barnes, furnisher, Sheffield. It is not often one finds the motor cycle put to the purpose of conveying suites of furniture, and the owner of the machine is to be congratulated on utilising his machine to such good purpose. "In these days there is an excuse for overloading, although the A.J.S. always takes the big loads without faltering," says Mr. Barnes.



WHOLESALE THIEVING OF MOTOR CYCLES.

A batch of stolen motor cycles outside the police garage at Ilford. All these stolen machines have been identified, their owners have been informed that they have been found, and the machines will be returned to them shortly. When the case was tried at the Old Bailey, the prisoner, Frank John Bennett, pleaded guilty, and was sentenced to four months' hard labour. In the course of the trial it transpired that he had deserted from the Army. He had also been the 9 st. 4 lb. boxing champion of England. Among the machines are a Sun Villiers, New Hudson, Abingdon, King Dick, Douglas, Indian and Enfield.

0 Fine for using Petrol.

F. W. Rumball, a New Cross motor clist, was fined £[illegible]0 at Greenwich last eek for using petrol on a motor cycle d for exceeding the speed limit. P.C. ollier, in evidence, said the defendant's atement that he was using the machine r travelling to work at an aircraft ctory was untrue.

oman Despatch Rider's Smash.

A W.A.A.C. motor cycle despatch der, attached to the A.S.C., M.T., staff epot at Grove Park, was rather badly jured by a collision with a motor lorry Bromley last week. She was taken to hospital suffering from injury to her ead. Part of the frame of the machine an overhauled W.D. Triumph—was roken by the impact.

he A.C.U. and the New United Council.

On another page of this issue we pubsh the explanation given by the A.A. its standing aloof from the new nited Council. At a meeting of the eneral Committee of the A.C.U., held n February 28th, it was decided that ne A.C.U. should follow the lead of the .A. The reason given was very similar that given by the A.A.

he Institution of Automobile Engineers.

The sixth ordinary general meeting of he Institution of Automobile Engineers ill be held at the Royal Society of Arts, ohn Street, Adelphi, W.C., on Wednesay, March 13th, at 8 p.m., when Mr. . L. Martineau will read a paper entitled "Nomography, with a Few References to its Use in Engine Design."

Cards of invitation to the meeting can e obtained on application to the secreary of the Institution of Automobile Engineers, 28, Victoria Street, S.W.1.

The Magneto Question.

Readers interested in this matter should read carefully our leader on the subject, and also the important letter from the Chairman of the British Ignition Apparatus Association published in our correspondence columns this week.

"The Autocar" Red Cross School at Vevey.

Lt. Michael A. J. Orde, R.F.C., son of Mr. Julian Orde, the secretary of the R.A.C., has now joined Lt. Wallis in the management of the latter's school of motoring. We have already referred to this school, and repeat our request that readers will help with subscriptions the excellent work being carried on.

Monitor in Place of a Tank.

At a meeting at Barrow to consider the raising of a quarter of a million pounds during Business Men's War Bond Week the Mayor stated that Messrs. Vickers have promised to build a model monitor to take the place of a Tank in raising the funds.

Death of Mr. Roland Marston.

We greatly regret to learn of the death of Mr. Roland Marston, who died suddenly a few days ago. Mr. Marston was only forty-five years of age, and was closely associated with the motor and aeroplane radiator department of Messrs. John Marston, Ltd., the manufacturers of the Sunbeam motor bicycle. He took a prominent part in the municipal life of the town of Wolverhampton, and in other public work. Owing to his energy and skilful management, the radiator department of Messrs. John Marston, Ltd., developed into an extensive business. He leaves a widow and one son, to whom we extend our deepest sympathy in their loss.

North-Eastern Automobile Association.

The report of the meeting of this Association for 1917 has just been published. Naturally there is little of real motoring interest contained in the report, but we are interested to note that the committee is giving its attention in all seriousness to the attention of fuels. This in itself is a good sign, as too much attention cannot be concentrated on this all-important subject.

The motor cycle section of this Association is now completely in abeyance.

Training of Discharged Soldiers.

This Association has also interested itself in the employment of discharged soldiers, and is appealing through the columns of its own journal for members who are willing to allow to discharged soldiers facilities for learning the business of chauffeuring in company with members' present drivers.

National War Funds.

The National Relief Fund (distributed £3,783,657)	£6,332,109 0 0
British Red Cross	9,169,627 13 2
Tobacco Fund	149,117 0 0

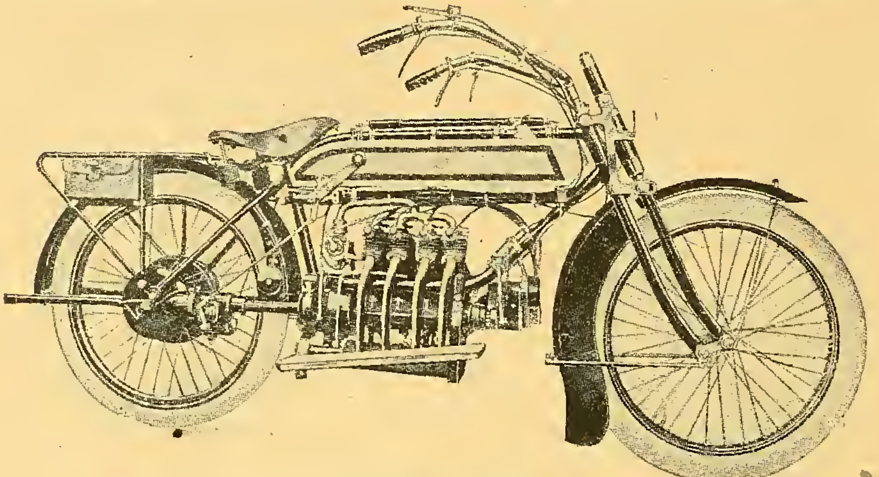
Motorists' Protection Association.

We are advised that Mr. Fred Haigh, 34, Castle Street, Liverpool, has been appointed honorary district secretary for the proposed organisation to be called the Motorists' Protection Association. Particulars of the suggested policy of this Association have already appeared in these columns, and we are informed that between 400 and 500 motorists have sent in their names as supporters. It is proposed to hold an inaugural meeting in London on March 14th. No definite subscription has yet been fixed, so that at present supporters do not bind themselves to become members later on.

The Four-cy
and

POSSIBILITIES AN
FOUR-CYLINDI

FOR some years past the writer has been foretelling both in the columns of this journal and to his sceptical motoring acquaintances the eventual triumph of the four-cylinder motor cycle over all other types on the road, therefore it may not come amiss to indicate wherein the "four" has failed in the past, and to throw out some suggestions as to the lines on which the modern "four" might well be produced. It may be advisable to mention that the opinions expressed herein are founded on a four-cylinder road experience dating from the earliest models, augmented by several years of close acquaintance with one of the few repair shops specialising in four-cylinder motor cycle overhauls.



The latest model F.N., of 7-9 h.p., embodying many improvements on the old type, and spoken of highly for sidecar work.

In the past it has been left largely to the F.N. to fight the battle for the "four" in this country, and, whilst such machines as the T.M.C. and the Pierce have had their admirers, they departed to such an extent in their general construction from accepted principles of motor cycle design as to require but little notice in any practical consideration of the four-cylinder cycle *as a pure motor cycle*. By that it is intended to imply that hybrid vehicles, half-car and half-cycle, however great their merits, are unlikely to become serious rivals to present-day types, if only for the reason that the purchasing public are apt to be surprisingly suspicious of departures from conventional type, characterising as a "freak" that which their eyes are not accustomed to see in the hands of the multitude. To command the necessary market, it will be essential, therefore, to wean the public gradually to new ideas, and in such details as frames, tanks, and general layout to preserve, as far as possible, in the first British "fours" the semblance of the present-day standard single or twin.

The Engine.

The capacity of each cylinder in a motor cycle "four" must necessarily be extremely small, and the smaller the capacity of the cylinder the greater is the necessity for extreme efficiency. Following the well-advised practice of the light car world, the four-cylinder cycle power plant should be a high-efficiency engine that "revs," as any attempt at a slow-running power producer would be almost an impossible proposition in the limits of a motor cycle frame. A revving "four," with its even torque, permits of a higher compression ratio than is possible with a single or twin of the same total capacity, and high compression means greater efficiency from each small cylinder, improved total power output, and more miles per gallon. It has been the writer's experience that most of the troubles in the old F.N.

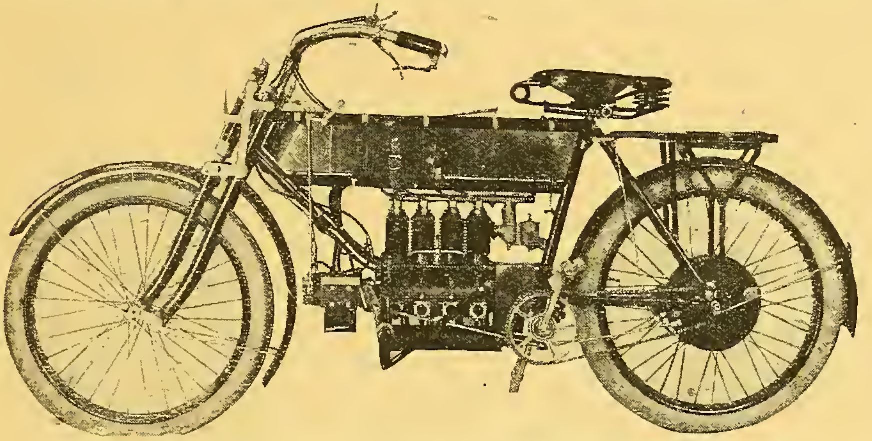
standard.

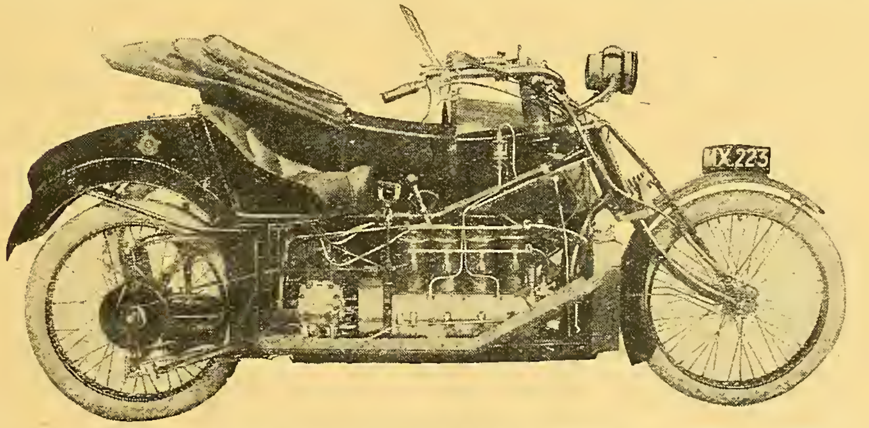
The advent of the tiny "four" will direct attention to the deficiencies of present-day motor cycle induction systems. What will function well enough in the carburetter line on a big single or a twin is hopeless in a little "four," where each cylinder must receive its correct proportion of properly atomised fuel constantly and regularly. The writer has seldom come across a four-cylinder motor cycle that, immediately on being started up from cold, would fire regularly on all four cylinders without hunting or missing. He has heard this fault attributed to sticking automatic valves, dirty distributers, sooted plugs, choked filters, etc., but very seldom has the root cause been mentioned—an improperly designed induction system. Little insistence seems to have been made by the motor cycle press upon the importance of pipe area and streamline contour in induction system design. Designers of earlier four-cylinder motor cycle engines were content to run a straight pipe over the cylinder heads, with four stub pipes *of the same diameter* branching off to the cylinders *at dead right angles to the main pipe*. That one ever got regular firing at all on these models was due to the volatile character of the spirit in use in those days, but present-day petrol finds the obstacle race to the cylinders too much for it, and it is common to see riders of old models warming up at appalling "revs" on the stand before venturing on the open road. Then came the day of graceful curves and globular swellings—all very artistic, but rarely arranged in conformity with any apparent recognition of the law of motion, so far as the mixture is concerned.

It has puzzled many riders of recent model "fours" to know why the two end cylinders get hotter and keep cleaner than the central two, and instances have been known in which mechanics, attributing this peculiarity to unequal lubrication, have gone to the trouble of fitting separate oil leads direct from the oil tank to the end compartments of the crank case. It has rarely occurred to riders that the two end cylinders are doing an undue proportion of the work, mainly because the induction system is so arranged as to feed the end cylinders at the expense of the other two.

In view of a discussion some time ago in these pages as to the merits or demerits of long and short induction pipes, it may interest readers to know that the writer, approaching this subject with an open mind and without any pretensions to higher training in engineering, found in practice that a main induction pipe on the long side gave the best



The Belgian 4½ h.p. F.N., a motor cycle that was popular in many countries as long ago as nine or ten years.



The T M C., the only British our-cylinder motor cycle that attained any degree of success.

The Four-cylinder of Yesterday and To-morrow.—

general results, but that the differences observed as the result of increasing or decreasing the length of the induction pipe became of very minor importance in relation to the problem of pipe-direction and the proportion of pipe-diameter of branch pipes to that of the main pipe.

For reasons too lengthy to be detailed here, the writer can see no future for the two-lever carburetter on a four-cylinder motor cycle. The single-lever automatic carburetter possesses certain advantages as regards a "four," which will make its use universal.

Scavenging.

No obstruction must be placed in the way of the rapid clearance of the burnt gases from the cylinders. What has been said about induction pipes applies with almost equal force to exhaust pipes. The 7-9 h.p. F.N. is an instance of a well-designed exhaust system, while its predecessor, the 5-6 h.p. model, secures extreme silence at the expense of an appreciable amount of back pressure. The effects of back pressure on a small "four" are of much greater importance than on a single or twin of similar capacity.

Transmission.

Judging by the correspondence columns, four cylinders and shaft drive are inseparable in the minds of the majority of riders, and one might even conclude that the main advantage of the four-cylinder power unit lies in the fact that it lends itself readily to shaft drive. In the hands of an expert driver, who does not place undue strains on any part of his combination, and to whom even a minor collision is a thing almost unknown, the shaft is perfection, but in the hands of the average man it is not likely to enhance the maker's reputation. It must be remembered that the back wheel of a heavy combination is subject to quite exceptional strains. It has to take the bulk of the weight, the twisting strain of the sidecar, and the driving effort, and it is housed in the best of machines in a somewhat flimsy fashion. Moreover, it must be readily detachable for tyre repairs. The superiority of the shaft is only apparent when the crown and bevel are exactly adjusted. Even an expert cannot fake a quiet adjustment when a machine has had a fair amount of careless handling, and the lining up of the shaft after an encounter with some heavy object is a job which the average motor cycle repairer likes to see taken to a rival garage. Most riders can tinker up a broken belt or chain by the roadside. Few would be able to do much to a troublesome shaft.

Apart altogether from the question of damage to the shaft, it is a harsh form of drive when the engine is in a sulky mood and given to erratic firing. The snag of a chain is unpleasant, but the knock of a shaft is akin to the conk of an overloaded single. Again, the replacing of the back wheel after a tyre change by the roadside—especially in wet weather or failing light, and tyres usually choose such conditions for a display of frightfulness—is a delicate operation, and the writer has unpleasant recollections of such incidents, where even the superlatively foolproof design of the 7-9 h.p. F.N. inspired a few epithets that would not have disgraced Capt. Kettle in his prime.

In short, therefore, since it should be the manufacturer's aim to construct the machine that will give least trouble in the hands of the average man, a chain drive of the Henderson type would appear to be the most suitable drive.

Lubrication.

If the British manufacturer finds the sump and pump system, as used on the 7-9 h.p. F.N., too costly to make, let him above all else avoid the drip feed almost universal on singles and twins to-day. The old-fashioned hand pump, if crude, was efficient. Drip feed on a four-cylinder is quite inefficient, unless arranged with an array of separate feed pipes, which are ugly, complicated, and none too dependable.

Frame.

The four-cylinder machine is usually of long wheelbase, and the tendency to side-play in the spring forks is, therefore, increased. A fork of great lateral rigidity is essential. A certain amount of resiliency in the fork might well be sacrificed to lateral rigidity. The writer may have a bee in his bonnet, but it is his opinion that future experiments in this direction would be better directed at stiffening the forks and springing the handle-bar. It has always been a source of surprise to him that the Enfield people did not continue with their spring handle-bar, which, with some mechanical restriction of its vertical motion, would have been beyond reproach.

American, Continental, and British Ideas.

One can say that the two best four-cylinder motor cycles on the pre-war market were the Belgian 7-9 h.p. F.N. and the American 10 h.p. Henderson. Each was typical of the country of its origin—the Belgian machine standing for grace in design, superlative finish of details, minimum weight, and maximum efficiency from medium cubic capacity, while the American subordinated beauty of outline and delicacy of detail to cubic capacity, speed, and that simplicity of operation which renders a machine proof against fools, but robs it of its individuality. Is it not possible for the British manufacturer to find the *via media?* We require somewhat more cubic capacity than the F.N. and somewhat less than the Henderson; something more robust than the Continental product, but less rugged than the American—in fact, we want a product of the British mind, which alone seems able to rise to the conception of beauty, strength, and efficiency in one comprehensive whole.

H. E. Thompson.

* * *

Another Method of Renovating a Tank.

During what promises to be a long vacation many motor cyclists will overhaul and renovate their mounts in anticipation of good times to come.

The following method of redecorating a tank can be strongly recommended for its simplicity, excellent effect, and ease of execution.

The lining, which is usually the great obstacle, is overcome by what I believe to be a novel means, and gives a result practically, if not equally, as good as the professional job.

The tank should first be thoroughly scraped and cleaned down with fairly coarse glass paper. Paper is first cut to the shape of the panels desired and stuck in place with gum or flour paste.

Using a good quality paint (not enamel) and a soft camel-hair brush, the top and sides are first painted.

When the surface is entirely covered remove the filler caps and support the tank by placing the fingers inside while the bottom is painted. Hang up to dry for forty-eight hours in a place free from dust. A second coat may then be applied. When this is dry remove the paper panels, and trim the edge of the paint with a penknife and a ruler. This should leave a sharp, straight edge.

Lay a piece of cardboard along the edge and, with a comparatively dry brush, carefully paint the panels the desired colour. A slightly ragged edge does not greatly matter, as this is afterwards covered with a line.

When dry a second coat is applied. Leave this to dry for three or four days, when the lining may be taken in hand.

For this a drawing pen is required somewhat similar to the one illustrated.

Drawing pen used for lining tank.

A little paint is put in an egg cup and thinned slightly with turpentine.

Adjust the points of the pen to about $\frac{1}{16}$in. apart by means of the screw.

Mark faintly with a pencil the desired line and then go over it slowly and firmly with the pen. The points should not be allowed to touch the ruler, but kept just clear.

The curves at the rear end of the sides and the small front panels are made by first cutting cardboard to the correct shape and using as the ruler. A smaller piece is placed underneath to lift it clear and obviate the risk of the paint running under the edge.

Any lettering should be outlined in pencil, followed by the pen and ruler. The letters are then filled in with a small brush or the side of the pen.

They can, when dry, be lined in colours with the pen. Leave the tank hanging up for about a week and then apply two thin coats of varnish. This should be applied evenly with a rag and cotton wool pad, and each coat thoroughly dried.

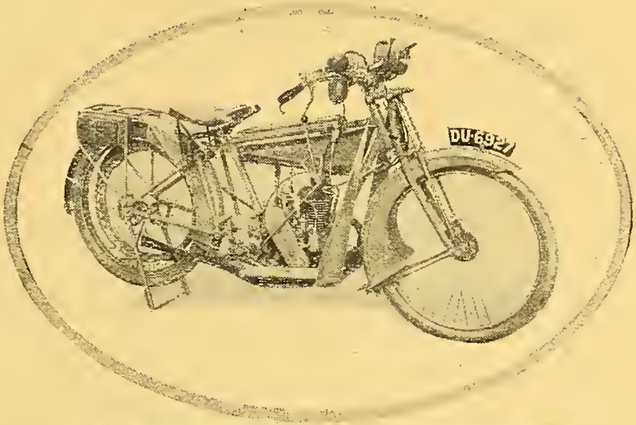
If reasonable care is exercised a smart and durable surface will be obtained ready for the days of plenty which we all hope are not far distant.

T. Thearle.

EXPERIENCES WITH LIGHTWEIGHTS.

SOME COMPARISONS AND OPINIONS.

A lightweight of 1901, the type of machine on which the author tasted his first experience of motor cycling.



A well-equipped lightweight of to-day—the rear sprung Allon two-stroke.

I HAVE always looked on the lightweight motor cycle as the ideal machine, particularly for the business man who requires a machine for the ordinary everyday round of commercial life, and as a ready means of gaining healthy recreation during the week-ends. When I look back and compare my first lightweight fitted with a 2½ h.p. Minerva engine with my present mount, a modern two-stroke machine, I can do nothing but wonder at the marvellous strides that have been made in bringing the lightweight to its present state of efficiency as a reliable go-anywhere machine.

How many miles I pushed that old relic of the past I should not like to speculate; the weird knack its accumulator possessed of transferring acid to my clothes, with anything but good results; the way the contact breaker had of sticking every mile or so, and in addition endeavouring to turn itself into a miniature crank case in the way it had of accumulating oil; the tiny belt, and narrow pulley that gave up business at the slightest sign of wet weather, and the automatic inlet valve, the chief function of which seemed to be to stick to its seating, and there remain: these were the ordinary affairs of life. Indeed, they were the days of the lightweight enthusiast! Many a Saturday afternoon have I wheeled the machine out of its stable for a run (most of the running, by the way, being done by me at the side of the machine), only to find that something was not "quite in order." If you were lucky the eventual result was a run of perhaps half a mile without mishap; if you were not, you never got beyond running the engine on the stand.

Resignation and Resuscitation.

I "carried on" with this 'bus for months, but came to the conclusion that as a ready means of speedy locomotion the lightweight motor cycle was not altogether "it." I gave it up, and it was not till the end of 1913 that the fascination returned, and I invested in a "Baby Levis." I shall never forget the delightful feeling of sitting across this little miniature and "paddling off" for the first time. I had one of the first of these machines in the district, and when there were some half dozen of us with them, we formed what was practically a "Levis" club, and no small excitement was caused in those days when we (including a lady) were on the road. The noise of half a dozen two-stroke engines on the move was decidedly a novelty, and the questions I have answered respecting the running, etc., of this class of engine would fill a book. I ran this machine for over 8,000 miles, the only expense for replacements being 1s. 6d. for a new inner cable operating the compression release valve. I had absolutely no trouble, although I treated the little bicycle in anything but a proper manner. I used to take a passenger (our combined weight being 21 stone) seventy-five miles practically every Sunday afternoon, and the way the little engine pulled was a marvel. I have run it to a standstill through overheating, but after fifteen minutes "rest" it was off again as fresh as ever. I could touch forty miles an hour solo, and thirty-five with a passenger. What a difference from the old Minerva days! I eventually sold this machine locally, and it is running about now as well as ever, its new owner having nothing but praise for it.

Experiences with the Petroil System.

Although perfectly satisfied with the little Levis, I was anxious to try a "Petroil" lubricated machine, and invested in one. This I found difficult to start unless the petrol was turned off about a hundred yards before the last stop, as any petrol left in the float chamber evaporated, leaving behind the oil, which on restarting generally choked the jet. The mixture also had a way of creeping all over the machine, leaving behind a dirty oily mess. The engine itself, however, ran really well, and had a splendid petrol consumption. What made me give it up was the way it wore out bearings, 2,000 miles being sufficient to make the main and big end bearings very bad, although the gudgeon pin brass did not suffer to any great extent. After rebushing it was just as bad when the same mileage had been covered, although more oil was used than recommended by the makers.

I next returned to my first love, and this time tried a 2¾ h.p. Modèle de Luxe fitted with two-speed countershaft gear. I found this machine an excellent

Experiences with Lightweights.—

"puller," but not much faster than the Baby. The extra power was most useful when taking a passenger—in fact, I could climb most of the hills in the Eastern Counties on top gear.

A Four-stroke Interlude.

Hearing a lot about the 2½ h.p. J.A.P. four-stroke engine, I sold out and bought a New Imperial J.A.P. with two-speed gear. This turned out to be a fine machine, very reliable, and much faster on the level than any of my previous mounts. After a bit of tuning I could nearly touch fifty, but, of course, could not keep it up. Another great point in its favour was a petrol consumption of 130 m.p.g. I had thousands of miles of reliable running out of this machine, and eventually sold it, since when I have owned and ridden some twenty makes of various lightweights, both two and four-strokes. Practically all were highly satisfactory, one in particular, an Allon two-stroke, being particularly good. This machine, with its original design, is certainly the outcome of much experimenting, the only thing I could find fault with being the front band brake, which was rather fierce when suddenly applied in an emergency.

Review.

From the experience I have gained with twenty-five or so machines, I have come to the conclusion that there is very little to choose between any of the first quality lightweights of the present day, and, further, the lightweight has come to stay. The only real trouble I had was with the first petroil lubricated engine, but on another machine I had fitted with the well known Villiers power unit, and lubricated by the same method, I had no trouble, the engine doing some six or seven thousand miles without rebushing, so that I can only attribute my trouble to bad design, and not to the system generally.

To the novice there need be no question of fear if he buys a machine turned out by a maker with a reputation. If you are an absolute beginner possibly a two-stroke would be better, as there are so few working parts in this type of engine, and decarbonising is simplicity itself. A two-stroke also has the advantage of being light on tyres, due to the more even running of the engine, while in favour of the four-stroke you have a better petrol consumption and more speed—the former no small advantage in these days.

A two-speed gear is very useful, and in some parts of the country absolutely necessary, but I hope to see in the near future a neat three-speed gear box incorporated in the really first-class lightweight. In my opinion, the difference in ratio between the gears of the present two-speed box as fitted in general is too great, and creates a tendency to "hang on" to the top speed in preference to changing down and letting the engine "rev" for dear life. Although I live in a fairly flat district, I frequently feel the need of a middle gear, which would be quite low enough for most traffic riding, and just right for the average hill. The bottom gear could then be used for starting and very bad hills.

The armies of both Britain and France are kept well posted with news. The photograph depicts a D.R. selling newspapers behind the line of the French Army. H. E. Plateau, who forwarded the photograph, says it is a great business with them (the D.R.'s). The paper being handed to the infantryman is *The Motor Cycle*, and the machine a B.S.A.

Some Sound Advice.

Most of the two-strokes I have had have been fitted with too large a jet to the carburetter. Some would only do about fifty miles to the gallon, and not two-stroke under twenty miles an hour on the level. A little care taken to find the correct jet, and a slight adjustment to the petrol level makes all the difference.

For two-strokes there is nothing to beat a good single-point plug with a stout central electrode. I have had multi-pointed plugs with thin electrodes burn completely away at the points when the engine was run at all hard for a few miles, and a great deal of apparent overheating is due to nothing but an unsuitable plug, the points of which become incandescent with consequent pre-ignition. Two-strokes are much more susceptible to plug trouble than are four-stroke machines, the reasons being, I think, fairly obvious, but any plug trouble can be readily and easily cured by changing the plug, and consequently is of only minor significance.

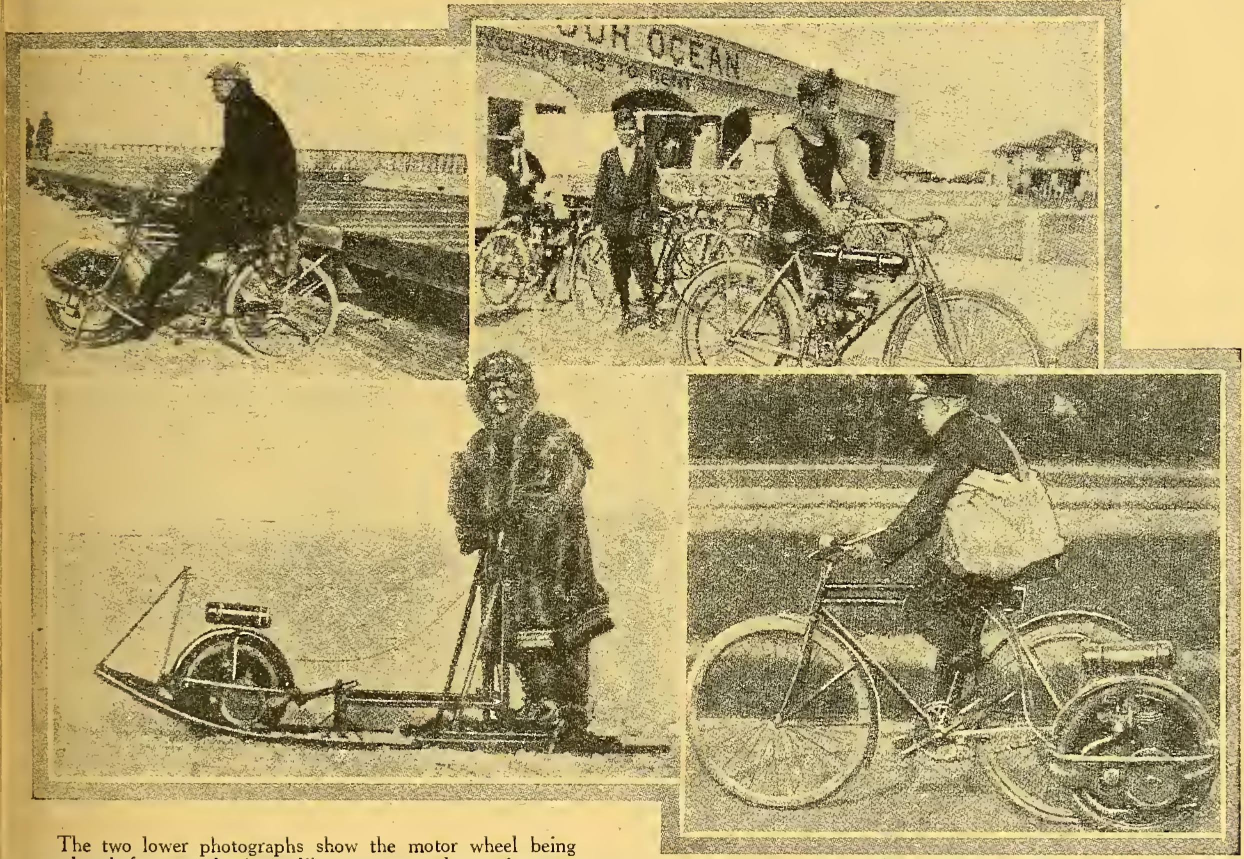
Always use a good brand of lubricating oil, it is much cheaper in the long run than rebushing, and do not forget that the cycle parts of the machine require regular attention. Treat your little machine with respect, remembering it has a big heart, and it will give you splendid service.

W.A.R.

THE MOTOR WHEEL.

Some Account of Light Motor Attachments for Pedal Cycles popular in the U.S.A.

THE motor wheel is becoming extremely popular in the United States. Imitation is the sincerest form of flattery, and it is gratifying to know that the first Auto-wheel was British, the successful Wall Auto-wheel having set the fashion. As we have previously mentioned in these pages, the American form of Auto-wheel is the Smith Motor Wheel, which is used in the same manner as the Auto-wheel. There is also a light four-wheeled vehicle on buckboard lines, driven by a Smith Motor Wheel at the rear and steered by an ordinary steering wheel.



The two lower photographs show the motor wheel being employed for very business like purposes, the arctic scene exemplifying its utility and adaptability to a very unusual degree. The upper photographs depict the Dayton power unit built into the front wheel, and the Cyclemotor, a small two-stroke design to fit the frame of a pedal cycle.
("*Motor Cycling and Bicycling*," *Chicago*.)

The Merkel motor wheel replaces the rear wheel of the standard bicycle and incorporates a self-contained spring suspension, which greatly adds to the comfort of the rider. The engine has overhead valves actuated by rocker arms and push-rods, and a long exhaust pipe.

The Cyclemotor.

The Cyclemotor has a compact two-stroke engine, and is designed to fit inside the diamond frame of a pedal cycle. The transmission is by belt, and a light belt rim is fastened to the spokes of the cycle. The petrol tank is carried under the top tube, and the complete unit is somewhat after the style of the attachment sold in this country by J. E. Smith, J.E.S. Motor Works, Gloucester.

The Dayton.

The Dayton is interesting in that in its form it somewhat resembles the early Singer motor bicycle of 1901 or thereabouts, inasmuch as the motor unit is built into the front wheel, though, of course, the Singer was very differently constructed. The Dayton has a refinement not usually found in these light attachments, namely, a multiple-disc clutch controlled by a twist grip from the handle-bar, which is naturally very useful in traffic. The amount of ingenuity displayed in the design of these light motor attachments, most of which do not exceed 20 lb. in weight, is quite surprising. There is no doubt that such attachments—few of which will propel a machine at a greater speed than twenty miles an hour, and will therefore not appeal to the enthusiastic motor cyclist—will do useful missionary work in educating cyclists up to the joys of the use of a properly designed motor bicycle.

We have already on various occasions pointed out that perhaps the most valuable service performed by the ultra-lightweight is that of securing recruits for the fully-fledged motor cycle.

LETTERS to the EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.
All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

A LUBRICATING TIP.

Sir,—I read with amazement that one of your readers had been mixing castor oil with engine oil. Perhaps by now he has found out that the two will not blend, and to do this is a patent process which is jealously guarded by those in the know.

He will doubtless find that he has an advantage in this so-called mixture, inasmuch as the castor oil being separate does the majority of the lubrication, while the other simply burns away. I would suggest he use pure castor if be can get it for nothing; the mixture only makes messes.

London, W.C. DAN.

BRITISH MAGNETOS.

Sir,—With reference to the interesting paper on "Motor Cycles," read by Mr. A. G. Pendrell, which appears in your issue of February 21st, we feel that we are entitled to take exception to his remarks regarding British magnetos. We have ourselves produced over 43,000 all-British magnetos since the outbreak of war, the bulk of which have been used by the British and Allied Governments, and we are prepared to prove that the mouldings we use are in every way equal to the German make.

We are sorry for the English firm who had to order tools, etc., for the 300 magnetos for motor cycles. We alone are producing 750 magnetos for single-cylinder engines per week, and shall be in a position to satisfy the demand for magnetos for motor cycles when the war is over, no matter how large that demand may be.

E.I.C. MAGNETOS, LTD
W. T Turner, Managing Director.

Sir,—The reference to British magnetos made in the paper read before the Coventry branch of the Institution of Automobile Engineers, and reported in your issue of February 21st, has been brought to our notice, and I have been asked to correct the misstatements made therein.

The author suggests :

1. That the insulating compound used for the mouldings is of inferior quality.
2. That the combined British output would scarcely supply Coventry alone.

The following are the facts :

1. The various British makes of insulating material have been submitted to the National Physical Laboratory, and the report on these has established that the material is equal, and in some instances superior, to the orignal German productions.
2. In September of last year a report on the actual number of magnetos produced in the various British factories during the preceding twelve months was asked for by a Government Department. This total was considerably more than the imports of Bosch magnetos for the twelve months preceding the war, as stated by the responsible official of the late Bosch Co. at a Government inquiry. That was six months ago. To-day the British output is at double that rate, and is still increasing. The concern of the British magneto manufacturers to-day is whether the motor trade at home will expand sufficiently after the war to absorb their outputs.

As regards the quality of British magnetos, the Government Departments to-day have ample powers to insist upon the high efficiency that is necessary. It is well known these powers are used to the full to obtain efficiency in everything appertaining to aero production.

We have been allowed to publish a few of the special performances of machines fitted with British magnetos, such as the record bombing flight to Constantinople and the destruction of the Zeppelins. But of more value in establishing the reputation of the British magneto of to-day is the fact that every day the lives of our airmen, and the very success of operations in the field, are dependent upon it.

I trust these facts will re-assure anyone who still has doubts on the ability of this country to produce its own magnetos after the war. PETER F. BENNETT,
Chairman, The British Ignition Apparatus Association.

PETROL SHORTAGE.

Sir,—Recently I visited London, expecting to see the streets rather bare of anything that used petrol. You can imagine my surprise when I found the streets full of taxis. The great majority were aimlessly wandering about looking for fares, and (would you believe it?) I saw several cars stop and discharge the occupants at a theatre. I saw three motor cyclists (military, of course). One can easily see with half an eye the aim of the authorities, to stop private motoring. Personally, I have no cause of complaint. I have a permit to buy petrol and use it. I work eleven and a quarter hours daily, and the ride of five miles each way to home energises and keeps me fit to stick unhealthy workshops, etc.

I think the present restrictions are crude, to say the least of them. Why not prohibit the use of petrol in taxis and suchlike when they *roam* about streets for hours on end looking for a chance fare? UNFIT.

Farnham.

Sir,—My idea in writing this letter is to impress on those people who think that the petrol shortage is faked, the vital importance of petrol to the aero engine manufacturer.

I hold a responsible official position in a department which looks after the production of aero engines, and am stationed at one of England's most famous manufacturer's works in the Midlands, so I really can state something of the truth about petrol.

There is something like 50,000 gallons used per month at this one factory alone for aero engine tests (endurance tests and ordinary bench tests).

This seems a great waste at first sight, but it is *absolutely necessary* to test each engine with *petrol* under actual flying conditions, which is done by means of the elaborate test beds which are used for the particular engine to which I refer.

We have not had a single instance of an aeroplane fitted with one of these engines coming down or being inconvenienced in any way with engine trouble, and the number turned out would make the Germans look sick if they knew.

Which would the perpetual grumblers prefer : petrol for their own use or petrol used to make the British aeroplane engine, the British aeroplane service, and the British airmen the finest in the world? It is something which does not require much thought, but simply answers itself.

We want petrol for dozens of such factories in this country *now*, and also for the very vitally essential transport traffic, both lorries and cars, serving the thousand and one needs of the industries, which are keeping the world going at the present moment, from this little country called England.

It is, of course, a pity that motor cyclists cannot obtain supplies of spirit, and I am as much "in the cart" as others, because I have been a constant rider since 1909, and own a big American twin at the present time, but, disagreeable as it is, I am obliged to leave my 'bus in Town, because I see very slender chances of obtaining a licence. JOHN G. GRENFELL.

AR RATIOS.

Sir,—In *The Motor Cycle* of January 24th I read a letter gned by "Triumph," and would very much like to know e writer, and how he managed to get the various engine rockets to give him the different gears mentioned.

I greatly desire to get about 4½ to I gearing, as I find e standard 5 to 1 is rather low for my work, and especially w that the finer weather is coming on. I might mention at I have ridden Triumphs since 1906, both as an owner d for the trade, so hope I know how to handle one. though great friends with several men in the trade, I ve so far been unsuccessful in obtaining a sprocket larger an 15 tooth.

F. A. CLARKE.

B.E.F.

BRICATION.

Sir.—"Chinook's" suggested design for crank case cooling February 21st would obviously aggravate the evil it is tended to relieve, because the interstices between the fins ould rapidly fill up with accumulated mud until the crank se resembled an inverted pre-historic mud hut! If the erage rider keeps his crank case in the average condition e all know so well, how is it to be expected he would uster the courage to tackle such a feat as "Chinook's" esign would periodically involve? Inside fins would almost eclude the possibility of thoroughly cleaning the crank se inside with any assurance that the "dregs" were enrely swilled out.

Belfast.

Vhy not fit an underscreen?—Ed.]

ENTRIFUGAL FORCE.

Sir,—"Ixion's" query as to the possibility of flying rough interstellar space can be answered without reference a flying expert. There is no ponderable medium of any ind in the empyrean. The utmost limit of our atmosphere about fifty miles. At greater heights than this gravitation so much reduced that the molecular velocity of the molelles of oxygen and nitrogen carries them off, if the line flight is radial. The moon has no atmosphere at all on is account; it was not big enough to hold the air it took ith it when it bade farewell to the earth.

However, this point is immaterial, for long before the mits of the atmosphere were reached the body of the too enturesome pilot would burst, owing to the absence of the ery useful pressure of 15 lb. per square inch we enjoy own here.

I should like to take this opportunity of saying that Mathematician" and "Lieut., R.F.A.," are mistaken in aying that "centrifugal force" is merely a convenient 'fiction." If a weight be tied by a string to a peg and hirled in a circle the peg will be broken if the weight r the speed be too great. The force on the peg is centrifugal orce, and tends to make it move (Latin *fugio*, I flee from) way from its position. If the weight were circling round n the inside of a smooth sphere, the sphere would press n the weight with centripetal force (Latin *peto*, I seek). n fact, under Newton's "Third Law" centrifugal force s just as real as centripetal force and no more.

A. L. GRAY.

OODS MADE IN GERMANY!

Sir,—I have been watching with interest during the last ew weeks the discussion *re* goods made in Germany, and may ay I was absolutely astounded when I read Mr. Ives's and his ollowers' letters. I did not think for a moment that there were such people in England. I heartily agree with Messrs. Turnbull and Waddington, also "A New Zealander." I may add that if Mr. Ives and company are childish enough to stop taking your paper because of that I am afraid they are only "cutting their nose to spite their face" and that they will take *no* motor journals at all, because every motor paper I know has followed your lead Wishing you every success, etc.

M 6148.

Chester.

Sir,—The letters under this heading in your issue of February 7th tempt me to butt in with a remark or two. The necessity to escape the scathing satire of determined "haters," like Mr. Geo. P. Waddington and others, is my apology for commencing on a personal note. When war broke out I was incorporated in a regiment of the "contemptibles," with whom I fought from August, 1914, until June, 1916. I was discharged in consequence of injuries but soon after joined the M.T. as a motor cyclist. I had a long spell up country with them, and I am prepared, if my health ever permits, to rejoin the boys in the trenches until the end. And with it all I back C. S. Ives every time! Absolute security for the future is the only thing that can save this war from being an unredeemed tragedy, and *no peace can give us such security.* It can only be obtained by a course of policy after the war which will tend to draw the peoples of the world closer, and by substituting good feeling for bad and friendliness for hatred. It is useless to say that the Germans are beyond hope, for one's reason surely tells us that a nation of 70,000,000 must, *in the main*, consist of decent everyday folk, however much *their* "haters" and militarists may have misled them; and, in any event, we have to live all on the same globe, so why not try and make the best of them instead of perpetuating hatred? By all means must our "basic" industries be conserved in English hands, but, with that reservation alone, we must meet German trade by improving our methods and business science, and not by a reactionary "protection" policy, coupled with petty spite, tending only to irritate international life, instead of promoting that close union of all peoples in which lies our only hope. And so I, in common with an ever-increasing body of soldier opinion, regret such statements as yours, firstly, because they are false to our original ideals, and, secondly, because all such statements will hinder the establishment of that secure future which is so ardently desired by the war-weary nations of the earth. After all, we fought, and so many died, not for German trade, but rather for honour and security.

Mr. Waddington will do well to remember that those who disagree with him on this question are not thereby necessarily worms, and that such talk is needlessly offensive; it might even be that hardships, sufferings, and the oft near presence of death have given an added insight to their political view of life.

H. G. M. NEWTON.

B.E.F.

Sir,—It seems a great pity that your notice respecting "Goods made in Germany" should have appeared in *The Motor Cycle*. It raises a vexatious question. The arguments for and against are equally intelligent, save for the bitter personal attacks made by some of your readers who are least able to bring into play their faculty of reason. I appreciate sound criticism, and admire a candid critic, but to manifest so much bitterness and heap contempt upon a fellow-correspondent whose views run counter to our own is no virtue, and certainly unworthy of publication in *The Motor Cycle*. No other conclusion can be arrived at than that the spirit which gave birth to such impossible resolutions at the Paris Conference is responsible for the greatest tragedy in history. The European slaughterhouse is nothing of which to be proud, and this wave of national jealousy will disappear, as will your notice which has caused so much contention.

JAS. REECE.

Three motor cyclists attached to the Southern Command. They are all old riders. Their names, reading from left to right, are Sgt. Mayne, Cpls Swan and Jeffery.

FLYING FACTS AND THEORIES.

Sir,—I have read the articles on the above subject with much interest and intellectual profit, and now, for the first time, I find myself unable to agree with one of Mr. W. G. Aston's conclusions.

On page 200 the following sentence is to be found: "If the gust lasted indefinitely, that is to say, if the gust became a steady relative wind in the direction shown by the arrows in fig. 2, the machine would tend to fly level, *i.e.*, keeping its centre of gravity the same height from the ground (after its appropriate relative speed had automatically adjusted itself) in the attitude shown in fig. 3." Surely this will depend upon the speed of the wind relative to the earth's surface and the speed of the aeroplane through the air. When these speeds are equal the aeroplane will not move relative to the earth, and consequently will maintain its altitude, but if the air speed of the aeroplane is in excess of the wind velocity the aeroplane will descend; if the reverse obtains, it will rise tail first. Let us take an extreme case (often useful in mathematics), and suppose the wind to be vertically upwards and the nose of the aeroplane to be pointing to the ground. The results will then be obviously as I have stated, and the aeroplane will only retain its altitude when its air speed equals the wind velocity.

Please note that I am not suggesting that the conditions of this extreme case can be maintained.

There may be some forces of which I am ignorant bearing upon this question, and if Mr. Aston, from whom I have learnt much, can enlighten me I shall be grateful.

JOHN HOLLAND.

EXHAUST POPPET VALVE DESIGN.

Sir,—Will you kindly allow me to reply to Mr. de Lissa, whose letter "*Re* Poppet Valve Design" appears in *The Motor Cycle* of February 14th? I feel very much indebted to Mr. de Lissa for so courteously and lucidly explaining why my M.A.G. gave trouble. First, I wish to make it quite clear that, in my opinion, the de Lissa is the only valve of this type which is really worth considering. The principle is quite correct, and I agree with Mr. de Lissa that it is as well to leave the valve alone. It runs cool and does not require grinding. Therefore, why do it? I ground my valves because of pitting due to road dust, etc., and I wish to repeat what I said in my last letter, *i.e.*, I ground them in correctly. I used the M.A.G. procedure, and obtained the same results, namely, poor compression cold, and absolutely perfect compression when hot.

Now, when running slowly the popping I referred to was due to weak mixture, as could easily be seen by looking at the carburetter. Every time a pop occurred vapour was blown out, and therefore the low-speed was what we usually call blow-back. This is quite beyond the point. I believe I said distinctly that the pop which troubled me was due to the exhaust valves and at high speed. I quite agree with Mr. de Lissa that if the valves are not ground in correctly this easily occurs; but then, my valves are correctly ground in. My reasoning was that the valve spring pressure was not sufficient, and this was increased, a little at a time, until the popping was eliminated.

My remarks as to the impossibility of moving the valves when at full lift were misinterpreted by Mr. de Lissa, due to my incomplete description. What I intended to convey was that the spring was too stiff for the purpose. Whereas while at the bottom of the lift it was possible to move the valve by hand, at full lift the extra load imposed by the spring was so great as to make it impossible to do so without levers. I might assure Mr. de Lissa that the coils of the spring were far from touching, and were perfectly in line with the valve. To get back to the original criticism of the de Lissa system, it is not the valve that is wrong, but the lever operating it. This lever is the same strength as the inlet lever, but I think Mr. de Lissa will agree that the loads imposed are vastly different. My solution of the job lies in reducing the weight of the valve distance piece and using a spring which was weaker per inch movement, but which was compressed further in order to give the same load on the valve; in effect, a much livelier spring and fewer inertia forces acting on the valve, tending to keep it open longer than is essential. These inertia forces cause the popping, and in a fast solo machine such as mine safety valve action or popping becomes a great nuisance.

Has Mr. de Lissa ever seen a cinema photograph of valves working at high speed? I mean a photograph showing the valves working so slowly that the action of the valves can clearly be followed, whilst in reality they may be "all out." It is often possible to see valves with as great a lag as 90° while the engine still functions, though not properly. If so, he will realise why I lay such stress on light valves and springs giving just sufficient load and no more.

In conclusion, I wish to make it quite clear that I am not prejudiced against the M.A.G., except in its exhaust valve rocker levers. These, in my opinion, are the only weak points in an otherwise excellent production.

OLIVOS.

Acton, W3.

THE UNITED COUNCIL OF MOTORING ORGANISATIONS.

Sir,—I have been a practical motorist since the very early days of motoring, and have also had something to do with the founding of the clubs and associations that were such a strong feature of those pioneer times. I therefore take a real interest in the agitation to found a United Council of Motorists. I am tempted, therefore, to ask a few straight questions. First of all, what work have the promoters of the United Council done for motorists, as distinct from motor manufacturers, garage proprietors, and dealers in cars, tyres, and accessories? No doubt they and the organisations which they represent honestly intend to do their best for the automobile movement as a whole, but what percentage of them can claim to represent the owners and users of cars and motor cycles? Again, assuming that each of the organisations composing the United Council is to send even only one delegate to the Council, to what extent and in what proportion are the private owners and users to be represented? If the "trade" be numbered in tens, those upon whom it exists—the owners and users—may be counted in thousands. [We have already explained that the user element is to predominate.—Ed.]

Is it likely that the proposed United Council of Motorists will do anything for the thousands, as distinct from the tens, which cannot be done—possibly more efficiently—by the R.A.C. and the A.A. and M.U. working in co-operation? "Unity," you say, "is strength," but proverbial philosophy often trips when it descends from the general to the particular. It is only sometimes, for instance, that "in a multitude of counsellors there is wisdom." Twelve delegates might conceivably talk twice as much as six, or four times as much as three, but talk alone will do nothing. Apparently the promoters of the United Council are intent on a multitude, for it has been suggested, I see, that the Council, well supplied with delegates from a variety of "trade" bodies, should be reinforced by an addition, or additions, from the ranks of motoring journalism. One may fail to see why it should; but if needs must, will you, Mr. Editor, suggest that there is any one man who could successfully hold a brief for the whole of the motor press? And, if not, are we to have half a dozen or more journalists on the Council?

Reading the latest comments upon the informal conference of February 1st, I see a strange insistence on the fact that the manifesto submitted for discussion "emanated apparently" or "emanated primarily" from the Motor Trade Association. *Was this conference convened by the Motor Trade Association?*

In any case, can it be pretended that it was convened by anybody who had the least concern for the interests of motorists as motorists, and not as purchasers and users of cars, cycles, or accessories?

United action, in anything, to serve any purpose, must be good. But, however anxious I may be to give the promoters credit for the best intentions, I feel that I, and at least a hundred thousand other users, in happier days, of cars and motor cycles, should know more of the antecedents of the bodies from which this United Council of Motoring is apparently to be recruited.

I would like more evidence that such a Council can do anything that the present governing bodies cannot. If I and others are to be convinced that the proposed Council can serve any useful purpose, let me suggest that the constituent bodies of this Council, electing delegates to it, should show us their right to be regarded as representing those on whom the automobile movement and the automobile industry, manufacturing and selling alike, depend for their future continuance in business—*car and motor cycle owners and users*, at home and Overseas.

(Rev.) F. W. HASSARD-SHORT.

My Ideal T.T. Mount.

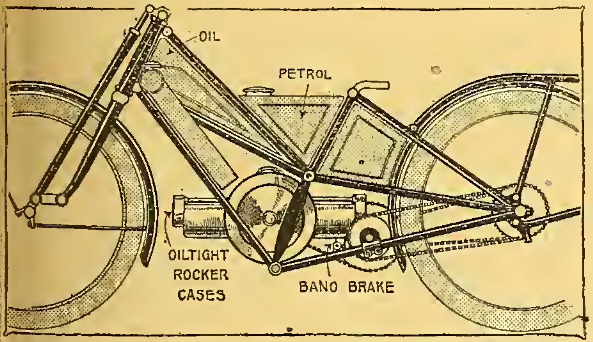
The following suggestive article, written by an experienced motor cyclist on his ideal machine, embodies some interesting points in the design of a machine intended primarily for road racing work. Our contributor definitely states that the T.T. is the ultimate end in his motor cycling life, and the machine he describes is designed with T.T. requirements kept to the fore.

I WILL admit at the outset that I have a strong prejudice in favour of the Scott type of frame, having tested its peculiar and undeniable advantages during several years' continuous riding of Scott machines, and having watched its marvellous performances in several T.T. races.

As nearly every motor cyclist knows, the T.T. course has certain marked characteristics—viz., long steady climbs, fast stretches downhill of indifferent surface, and numerous corners—and it was the Scott frame's peculiar capacity for successfully meeting the last two difficulties more than the type of engine fitted that accounted for its success.

If only we could introduce a well-balanced engine capable of very high revolutions for long periods into such a frame, we have theoretically a very promising combination.

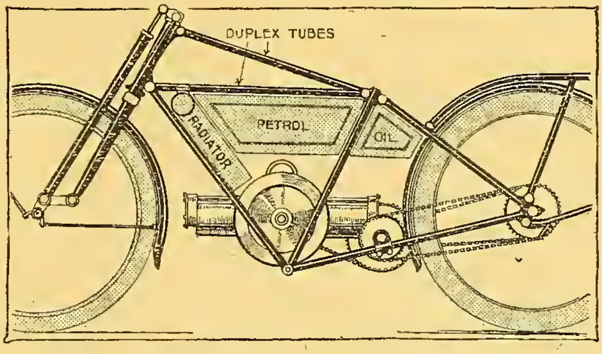
Whatever may be the pros and cons of water-cooling for touring machines in the hands of the general public, to my mind it has considerable claim on our very careful consideration for purely racing machines, where the ability of the engine to keep reasonably cool and at its most efficient working temperature during long periods at full load is of the utmost importance.



The frame design suggested in the accompanying article by "J. W. O." for a future T.T. mount.

Theoretically the most perfect power unit is the horizontally opposed overhead valve twin, but certain difficulties have arisen with the use of overhead valves in air-cooled engines which in practice have rather outweighed the advantages, viz., (1) liability of breakage [Very slight at present—Ed.] through overheating, and consequent damage to engine; (2) short period of accurate adjustment through excessive wear.

By adopting a proper system of water-cooling the liability to breakage can be practically eliminated. Anybody with any experience of o.h. valve water-cooled aero engines will vouch for the extreme rarity of valve breakages, and it must be remembered that an aero engine often works at full load for hours on end. Another important advantage of water-cooling would be the much greater reliability and longer life of plugs—possibly the most vital and troublesome items on a racing engine.



An alternative design by "J. W. O." for a future T.T. mount. The advantages claimed are dealt with fully in the accompanying article.

The second objection is more a matter of design than an inherent fault of the principle.

Why cannot the operating rods and rocker arms be completely enclosed, as is done in the case of the M.A.G. engines?

Variable Valve Timing.

Instead of a multiplicity of gears I have often wondered why sliding cams, giving varying degrees and angularity of opening and closing of both inlet and exhaust valves, have not been tried, the idea being to obtain more flexibility and steadier pulling power under load. Thus we could have an early opening and late closing for the exhaust valve for very high speed under light load, and a later opening for slower running and steadier pulling under load. The increased complication would be practically negligible, and the cams could be operated by a Bowden control from the handle-bar. As far as I can recollect, this system has never yet been tried on a motor cycle, although I have a recollection of it being tried on cars some years ago. In the hands of an experienced rider

My Ideal T.T. Mount.—

the results should prove interesting. What have some of our old T.T. experts to say to this suggestion?

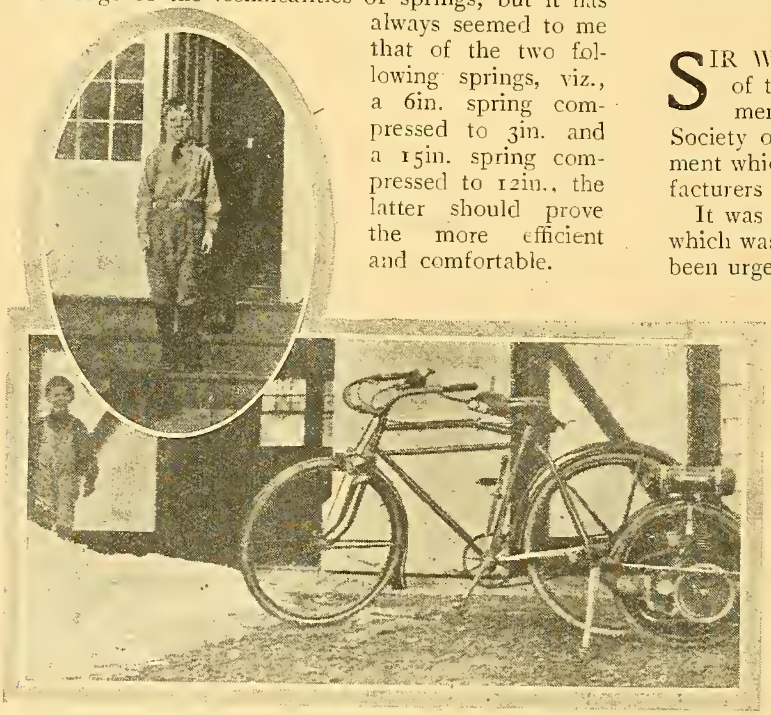
With regard to transmission, I think few experienced racing motor cyclists will disagree with me when I suggest a chain drive giving less trouble than present designs.

The Scott has shown what it can do with two speeds, and as the variably-timed engine I suggest should prove even better as regards flexibility and steady pulling under load, I vote for a simple type of change-speed gear without gear wheels, on the following lines, viz.: one noiseless pattern high-speed chain from engine to countershaft, and two slow-running roller chains to rear wheel, the change of gear being effected by a simple sliding dog clutch. This type of change-speed gear is very simple, and affords a considerable saving in weight over the orthodox gear box.

With regard to brakes. I make the rather revolutionary suggestion of putting two small band brakes *on the countershaft*, one acting through each chain and compensated with each other, both being operated by a single pedal. Front brake, small belt rim with shoe working on outside—Lea-Francis pattern.

Springing.

After a lengthy experience of most makes of spring forks, I have yet to find a better type than that formerly fitted to the F.N. lightweight. A movement of at least 3in. under severe road shocks is very desirable, and it is difficult, if not altogether impossible, to obtain this range with the usual short fork spring of the helical pattern. I claim no special knowledge of the technicalities of springs, but it has always seemed to me that of the two following springs, viz., a 6in. spring compressed to 3in. and a 15in. spring compressed to 12in., the latter should prove the more efficient and comfortable.



A Smith Auto-wheel used by an American school boy aged eleven years. He uses it for riding between his home and school. All mechanically-minded British school boys know they must reach the age of fourteen years before they can taste the joys of driving a motor cycle

It is generally admitted that the more efficient the front springing, the more perfect the control over indifferent surfaces, and consequently the higher the speed possible. I believe it is a fact that in several T.T. races the riders of some of the better machines could not let their machines out to their full capacity through sheer inability to steer them.

In conclusion, I would mention a few minor details, viz.: roller bearings throughout engine, foot-controlled oil pump for emergencies but automatic force feed for ordinary running, foot-controlled gear by rocking pedal, handle-bar controlled clutch, every nut spring-washered or split-pinned, three-ribbed tyres (Palmer or similar pattern), swing-up back mudguard flap as on Rudge, and spring saddle-pillar.

Suggested Advantages.

A few special advantages I would claim for my suggested design are as follow: (1) Exceptionally low centre of gravity, ensuring maximum speed in cornering; (2) a wonderfully efficient engine unaffected by overheating; (3) practically the whole of the weight centrally between the wheels; (4) a double-purpose engine for fast downhill work and steady pulling uphill; (5) an extremely efficient change-speed gear; (6) all control without moving the hands from the handle-bars.

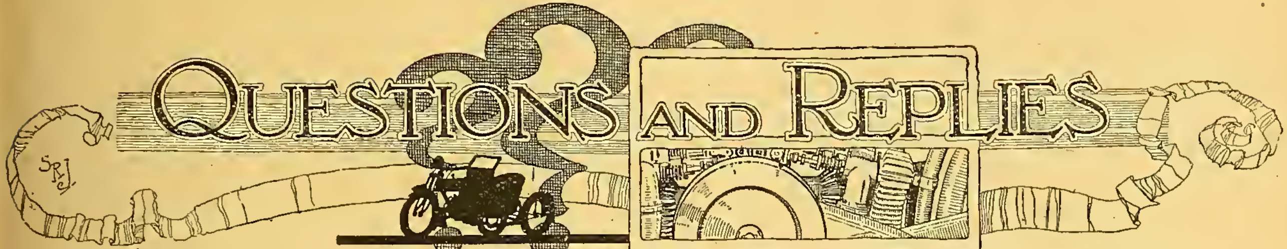
The great variation in design of power units, transmission, springing, and other details among the best makes shows that there is a considerable diversity of opinion, and I am strongly of opinion myself that by combining the best details of all the machines it is possible to produce a better and faster machine than any hitherto entered. J.W.O.

OVERSEAS TRADE.

SIR WILLIAM H. CLARK, Comptroller-General of the Department of Overseas Trade (Development and Intelligence), speaking at the Royal Society of Arts, described the functions of a department which was constituted for the assistance of manufacturers and traders in promoting their business.

It was a comprehensive attempt to solve a problem which was not a new one, but which for some years had been urged on the Government by the commercial and industrial community. The new Department was authorised to take action arising out of its commercial intelligence work in connection with the promotion of Overseas trade, subject, of course, to the exceptions that the larger issues of commercial and industrial policy were the concern of the Board of Trade, and that all matters affecting relations with foreign Powers must remain the concern of the Foreign Office.

Their organisation was, of course, far from perfect, but if, as they hoped, the foundations had now been laid on sound lines, the rest would follow quickly enough, provided the work were carried on with intelligence and energy, and provided always that they did not forget the important truth, viz., that a Government Department cannot help the commercial community efficiently unless it works in the closest co-operation with them.



QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

Cracked Parts.

(1.) Is it advisable to let an engine run with a cracked piston skirt? (2.) Does a cracked valve seating (exhaust) do the cylinder any harm, as it does not lose any appreciable amount of compression?—R.P.

(1.) It is not advisable to run any engine with a cracked piston skirt, although no damage will ensue if the crack develops into no more than a crack—*i.e.*, so long as the piece does not actually break off. (2.) The same is true as regards a cracked valve seating, but in both cases the crack is always liable to grow if left untouched, and this growth may be sudden.

Indian Gear Adjustment.

I shall be obliged if you will let me know if it is possible to adjust a two or three-speed gear on an Indian motor cycle road racer (1910).—C.V.P.

The adjustment you require is situated on the outside of the gear box, but we should advise you to apply to the makers—the Hendee Manufacturing Co., 366-333, Euston Road, London, N.W.—stating your difficulty, and asking them for an illustrated catalogue of the model you possess.

Steam Injection.

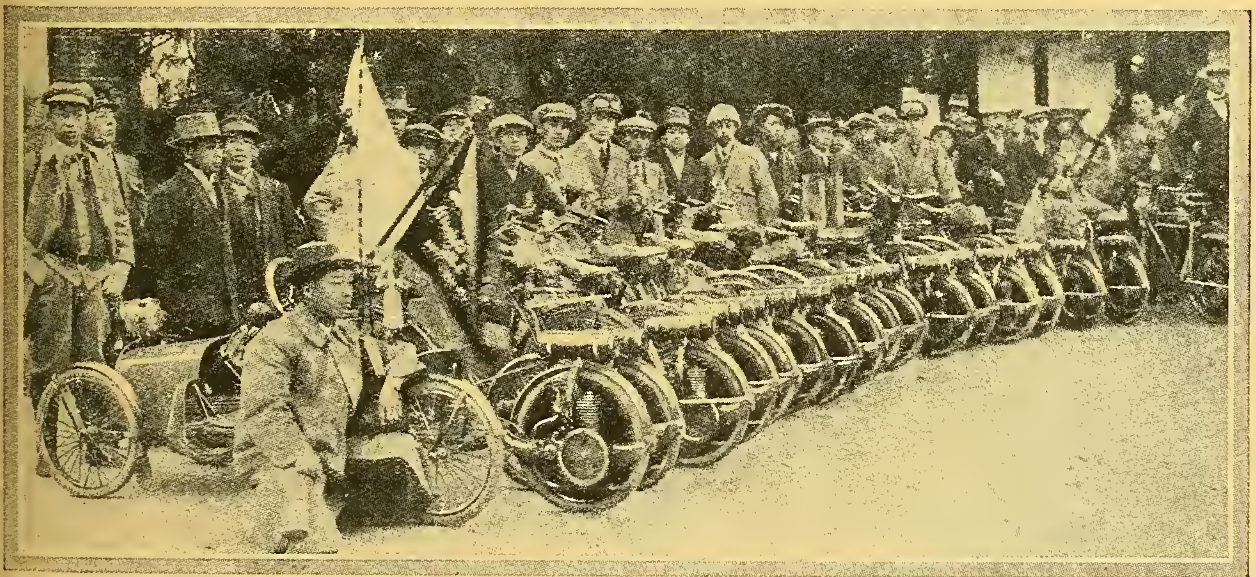
Will you please criticise and advise me on the following idea for fitting a steam injector to my motor cycle? (1.) After passing it round the exhaust pipe, lead the copper tube in at the extra air port of the Schebler carburetter so that the steam mixes with the gas in the mixing chamber. Would this be better than leading the steam in through the induction manifold or in at the main air intake at the bottom of the carburetter? (2.) Is it a disadvantage for the steam to enter in front of the throttle shutter on account of condensation? (3.) Is a small nozzle necessary, or merely the end of the copper tubing? (4.) What diameter tubing do you advise? (5.) What size would the water container have to be to run, say, 200 or 300 miles without refilling? (6.) The amount (roughly) of water injected? (7.) Is it necessary to feed the water under pressure? The container would be fixed approximately on the same level as the carburetter. (8.) Would a non-return ball valve be necessary?—J.L.F.

(1 and 2.) Leading the steam in through the induction manifold would be most likely to give satisfactory results. (3.) If you have a small nozzle you will need pressure to force the steam through it. If this can be easily provided a small nozzle would be an advantage. (4.) About $\frac{1}{16}$in. (5.) About a quart. (6.) The whole amount in the container practically. (7.) There is no actual necessity to feed the water under pressure, but the container should be on a lower level than the carburetter for preference. (8.) We do not think so; but it might be useful. We do not think the amount of heating to which you intend to subject the copper water pipe will be quite adequate for your purpose. It should pass round the exhaust pipe at least four or five times.

Magneto Juggling.

The angle of my magneto is set at 180°, and is worked off the half-speed wheel. Would driving it off the 2 to 1 wheel have the same effect as altering the angle to 90°? I want to use the same magneto (180°) to work an engine which is at present worked by contact breaker set at 90° and driven off the half-speed wheel.—N.H.

We take it that by the 2 to 1 wheel you mean the main driving pinion. If this is the case, your assumption is correct. If you have a magneto set at 180°, you may use it to ignite a twin engine of 90° driving the magneto directly from the mainshaft pinion.



Japanese motor wheel enthusiasts at Nagoya. Japan offers a big field for the motor cycle manufacturer, as the Americans have already realised. (See page 237.)

Books.

Have you a book—or can you recommend one—dealing thoroughly with the repairing of magnetos?—A.M.

So far as we are aware, there is no book dealing solely with the repairing of magnetos, but "Electricity and the Motor Car," published by Messrs. Iliffe and Sons Ltd., 20, Tudor Street, London, E.C.4, deals thoroughly with magnetos, and a fair amount of space is devoted to magneto troubles. "Motor Cycles and How to Manage Them," also published by Messrs. Iliffe and Sons Ltd., deals very fully with magneto ignition on motor cycles.

Cycle Car Questions.

(1.) Is there any objection to having a cycle car with two wheels at the rear and one in front instead of with one wheel at the rear? Why not one in front and two at the rear. The rear has all the weight and drive. (2.) What is the tax for a four-wheeled light cycle car?—R.P.

(1.) This is largely a matter of opinion. Experiment has proved that to have two wheels in front gives more satisfaction in general service, as two wheels behind need the use of a differential gear or only one wheel can be driven. The various arguments in favour of each type have been dealt with from time to time in *The Motor Cycle*. (2.) The tax on a four-wheeled car depends on the horse-power. For 8 h.p. up to 12 h.p. it is three guineas.

Hub Gear Queries.

(1.) I have obtained a petrol permit and licence to use my motor cycle while home on leave. Shall I require to have the Inland Revenue licence? (2.) Shall I require a driving licence before I can drive, or will my last year's one be good enough? (3.) Are the 1912 and 1913 3½ h.p. Ariel models fitted with ball bearings or plain bush on the crankshaft pulley end? (4.) Is the Ariel fitted with roller or plain connecting rod big end bearing? (5.) What sort of bearing has the crankshaft on the timing side? (6.) Will a three-speed hub gear fit the frame of this machine, owing to the kinked part for the belt rim? I thought this would foul the spokes of a three-speed belt pulley. Am I correct? (7.) Would the belt line on my engine and that on a three-speed hub gear be the same?—R.P.

(1 and 2.) You will be compelled to take out an Inland Revenue licence and also a driving licence if your existing licences are not current, *i.e.*, if they have expired. A driving licence lasts for twelve months from the date of issue, and not for a calendar year as is the case with an Inland Revenue licence. (3 and 5.) The majority of 1912 and 1913 3½ h.p. machines were fitted with plain bearings on the timing gear side and ball bearings on the pulley side of the mainshaft. (4.) The connecting rod has plain bearings. (6.) A three-speed hub can be fitted, but new belt and seat stays will also have to be fitted. The belt line of the engine and that of the three-speed gear are the same, or the belt line of the gear can be made the same as that of the engine.

Misrepresentation by Dealer.

In April last year I bought a 3½ h.p. twin James from a well-known London firm, which they represented to be a 1915 model, for £44, which was about its market value. In about a couple of months I was warned for Overseas again, and sold the machine to a friend as a 1915 model. He had considerable trouble with the machine, and when in communication with the makers discovered the fact that the machine left them in February, 1914. Now when I arrive home again my friend will naturally take the matter up with me, and ask me what I intend to do? Can you advise me of my position with regard to him and the dealers (I hold their receipt stating the machine to be a 1915 model)?—C.T. (Lt., A.S.C.).

In our opinion, you are responsible to your friend, but in your turn you can recover from the vendors of the machine, as it was sold as a 1915 model.

Petrol for Leave.

I believe it is now legal for people on fourteen days' leave to the United Kingdom from France to ride or drive motor cycles and cars for joy-riding purposes. If this be true, can you please tell me: (1.) May passengers (civilians) be carried? (2.) Must the driver have an up-to-date licence for driving and for the machine? (3.) May twelve (?) gallons of petrol, or rather a ticket for it, be had at the Petrol Controller's office in London?—V.T.A.

(1.) The carriage of passengers makes no difference whatever to the use of the machine, and if you have the right to use petrol you may take any passengers you wish. (2.) All licences, of course, must be up-to-date. (3.) You should apply for a petrol permit to the Petrol Control Dept., 19, Berkeley Street, London, W.1, about three weeks before you expect to come home on leave. If you have not this time at your disposal, you should write to the Controller, placing the full circumstances of the case before him, and expressing your intention to call on a certain date for the permit.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY.

During 1918 the restriction on the import of paper and paper making material is very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week.

That Inland Revenue Tax!

Will you kindly let me know if I shall have to pay the £1 tax for my motor cycle, as I can only use it purely for business?—H.P.

You will have to pay the £1 tax unless the machine is *constructed* and *used* solely for the conveyance of goods.

Electric Lighting.

(1.) Can you give me a sketch of how to wire up my solo machine from an accumulator to run with a bright head light and only a glimmer in the rear one; so that I can switch over to have only a glimmer both front and rear for use while leaving the machine by the wayside? My lamps are insulated. (2.) What would be the most suitable bulbs to use, candle-power and volt, etc.? (3.) What would be the best accumulator to use, volt and ampère hours and how many cells? (4.) Where could I obtain bulbs and accumulators? I have lamps.—R.P.

(1. and 2.) The answers to these queries will be found in *The Motor Cycle* of February 21st. (3.) We think you cannot do better than use any good accumulator of four volts, forty amps. The voltage of the bulbs will depend, of course, on that of the accumulator and on the principle of wiring. (4.) Any good agent should be able to supply these.

EXPERIENCES WANTED.

"B.S." (Salop).—3 h.p. Enfield. Efficiency of lubrication system, speed, maintenance of power, and general efficiency.

"C.E.T." (London).—Henderson and Zenith motor cycles, also Morgan Runabout. Consumption, reliability, tyre and transmission wear.

RECOMMENDED ROUTES.

Scorton to Rothbury.—H.B.

Scorton, Croft, Darlington, Ferryhill, Durham, Chester-le-Street, Newcastle, Morpeth, Rothbury.

Dewsbury to Edgware (London).—D.M.

Dewsbury, Wakefield, Doncaster, Bawtry, Retford, Tuxford, Newark, Grantham, Stamford, Norman Cross, Alconbury Hill, Buckden, Eaton Socon, Biggleswade, Baldock, Stevenage, Welwyn, Hatfield, Barnet, Potters Bar, Ganwick Corner, Boreham Wood, Elstree, Edgware.

Wareham to Lincoln and York.—F.T.A.

Wareham, Wimborne, Cranborne, Salisbury, Andover, Kingsclere, Aldermaston, Reading, Henley, Marlow, High Wycombe, Amersham, Chesham, Tring, Ivinghoe, Dunstable, Ampthill, Bedford, Eaton Socon, Stilton, Peterborough, Market Deeping, Falkingham, Sleaford, Lincoln. To reach York from Eaton Socon continue through Buckden, Alconbury Hill, Norman Cross, Stamford Grantham, Newark, Tuxford, Retford Bawtry, Doncaster, Ferrybridge, and Tadcaster to York. The distance is approximately 245 miles and 315 miles.

MISCELLANEOUS ADVERTISEMENTS.

PRICES.

ADVERTISEMENTS in these columns —First 12 words or less 1/6, and 3d. for every two words after. Each paragraph is charged separately. Name and address must be counted Series discounts, conditions, and special terms to regular trade advertisers will be quoted on application.

Postal Orders sent in payment for advertisements should be made payable to ILIFFE & SONS Ltd., and crossed & Co.

All advertisements in this section should be accompanied with remittance, and be addressed to the offices of "The Motor Cycle," Hertford Street, Coventry. To ensure insertion letters should be posted in time to reach the offices of "The Motor Cycle," Coventry, or London (20, Tudor St., E.C.4), by the first post on Friday morning previous to the day of issue.

All letters relating to advertisements should quote the number which is printed at the end of each advertisement, and the date of the issue in which it appeared.

The proprietors are not responsible for clerical or printers' errors, although every care is taken to avoid mistakes.

NUMBERED ADDRESSES.

For the convenience of advertisers, letters may be addressed to numbers at "The Motor Cycle" Office. When this is desired, the sum of 6d. to defray the cost of registration and to cover postage on replies must be added to the advertisement charge. Only the number will appear in the advertisement. All replies should be addressed "No. 000, c/o 'The Motor Cycle,' 20, Tudor Street, E.C.4."

☞ DEPOSIT SYSTEM.

Persons who hesitate to send money to unknown persons may deal in perfect safety by availing themselves of our Deposit System. If the money be deposited with "The Motor Cycle," both parties are advised of this receipt.

The time allowed for a decision after receipt of the goods is three days, and if a sale is effected we remit the amount to the seller. but if not we return the amount to the depositor, and each party to the transaction pays carriage one way. For all transactions exceeding £10 in value, a deposit fee of 2s. 6d. is charged: when under £10 the fee is 1s. All deposit matters are dealt with at Coventry, and cheques and money orders should be made payable to Iliffe & Sons Limited.

The letter "D" at the end of an advertisement is an indication that the advertiser is willing to avail himself of the Deposit System. Other advertisers may be equally desirous, but have not advised us to that effect.

SPECIAL NOTE.

Readers who reply to advertisements and receive no answer to their enquiries are requested to regard the silence as an indication that the goods advertised have already been disposed of. Advertisers often receive so many enquiries that it is quite impossible to reply to each one by post.

MOTOR CYCLES FOR SALE.

Accumulator Electric Lighting

Complete Set, 100/-

For Solo Machines. This set contains head lamp and tail lamp of the latest approved design, with adjustable handle-bar fittings. The box to fit on the top tube contains a 4-volt accumulator and a switch, giving sufficient light for the two lamps for approx. 10 hours at one charge. It, without doubt, fills a long-felt want for solo machine lighting.

Fresh Light on the Fuel Question.

A NEW committee to deal with fuel matters has recently been inaugurated. This consists of extremely capable representatives both from the Institution of Automobile Engineers and from the Society of Motor Manufacturers and Traders, and the name by which the committee is known is the Fuel Sub-committee of the Technical Committee of the Motor Industries. The formation of this committee coincides in point of time with rather important events moving in the fuel world of quite a different nature. We have at various times in the past suggested that the petrol interests—in other words, the Oil Ring—have been for a long time setting a determined trap to catch all benzole produced in their own net, the ultimate object being to secure a firm corner in the motorists' fuel market. There are, of course, other indirect inducements, but this is the sum of them all. This being the case, we venture to express the hope that the new Fuel Sub-committee will do its very best to counteract these efforts of the great Petrol Ring, and, while we do not for a moment pretend that the production of benzole after the war will ever make us entirely independent of all petrol, nevertheless the more benzole we have available the less will be the extent of our dependence on our arch-enemy, the Oil Ring.

At the present time the Oil Ring is approaching benzole producers with extremely attractive offers, the sum total of which will amount to the Oil Ring taking over the whole of the benzole produced. Thus, after the war, our dependence on petrol or on the products of the Petrol Ring will be as great as ever. It has been suggested that one end held in view by the Oil Ring is that after the war, if it has control of the benzole, it will be able to mix this benzole with petrol that would otherwise be unfit for use as a motor fuel; consequently the Ring will be provided with a market for some of its products at a very much higher price than these products will otherwise command. Also, as suggested in our parent journal *The Autocar* of March 9th, it is possible that the Oil Ring is looking rather further ahead than is evident on the surface, and that it has in mind the seizure of all benzole products so as to be able to prevent the use of alcohol as a motor fuel in days to come.

The use of alcohol as a fuel has been dealt with frequently in the columns of *The Motor Cycle* and associated journals. So long ago as 1906 experiments were carried out on this subject under the auspices of *The Autocar*, and these experiments were repeated at intervals and the results tabulated and preserved for the benefit of future experimenters. It has been shown that with our present engines and carburetters alcohol is of very little value, although in a specially designed engine, with a particularly high compression ratio, it is quite efficient when once the engine is started. Mixed with benzole, however, alcohol needs no special engine nor special tuning of any existing petrol engine. It could be purchasable in practically unlimited quantities, and is entirely miscible with benzole. With these two home-produced materials very little juggling is necessary to produce an almost perfect fuel—a fuel, indeed, that has many advantages over petrol. Consequently, present war against the subtle activities of the Oil Ring is a marked step in the development and introduction of alcohol as a common fuel. There are, of course, many permanent Government restrictions to be overcome before alcohol can be permitted as a regular fuel, but we have no doubt that in the course of time these will prove to be no insuperable obstacles.

Bearing all these facts in mind, we appeal again most vigorously to the Fuel Sub-committee to do its very utmost to counteract these specious proposals. The matter is not one that admits of simple solution, but the committee will at least have the satisfaction of knowing that any sound and logical suggestions are bound to receive the support of every motorist.

An index to the advertisements in this issue will be found on the page facing the back cover

A PLEA FOR BETTER STANDS.

Some Pointed and Suggestive Remarks on a Frequently Ignored Detail of Design.

AMONGST the many points that will receive attention on post-war models, let us hope that the rear stand will come in for its fair share; it wants it.

The ideal stand should embody the following features:

(1.) Base of sufficient width to ensure the machine not falling over when set up on uneven ground.

(2.) More supporting area to be provided at the point of contact with the ground, so that the stand will not sink into soft earth, such as a field or a gravel drive.

(3.) An automatic spring up and self-locking device.

(4.) Means of lessening the effort at present required to set up a heavy machine on its stand.

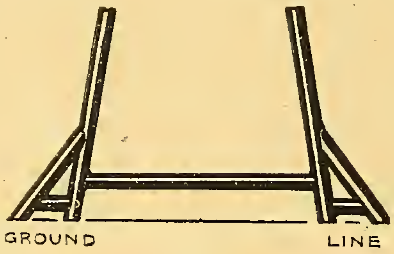

Fig. 1.

An improvement the author effected to the stand of a Douglas motor cycle.

As regards the first point: what on earth is gained by employing a narrow base such as many makers do? I have often wondered why it was done, but could see no reason at all. The fact remains, however, that many so-called high class machines possess a stand which is too narrow to support the machine safely on any but a level concrete or wood floor. I know a brand new P. and M. which tumbled over or was blown over twice while on its stand outside the owner's house; certainly the road was uneven and rather highly cambered, but so are many roads. The stand was taken off and the bottom crossbar cut right out; each leg was then bent outwards at the point where the tube joined the lug attachment to the frame, making the total base some 3in. wider; a new crossbar was then fitted and brazed in with satisfactory results.

As regards the second point. A few weeks ago I took possession of a 2¾ h.p. Douglas. This machine twice fell over when it was put on its stand on a level gravel drive. Certainly the drive was soft through the frost coming out, but drives in a thawing condition are not uncommon.

Welding the Tubing.

I took the stand off and had a piece of oval tube acetylene welded on to each leg, as shown in fig. 1. A bar of ⅝in. diameter round tube was also welded across between the old leg and the new addition; the base was thus widened and the supporting area more than doubled, for should the stand now be placed on soft ground it does not have to sink far in before the new short crossbar makes contact with the ground and carries its share of weight.

Why do manufacturers think that alterations of this sort should be left to amateurs to carry out?

It entails in every case re-enamelling the whole stand; in the case of the P. and M. this meant matching up a fancy grey-green and relining. Surely they do not think that a machine is improved by a few spills, or do they think at all, so long as they can sell their product at a high price?

A Desirable Type.

As regards point 3. Why should a rider be expected to stoop down and grasp an often muddy stand to pull it up into its place, or perform contortions with one foot to achieve the same end, and even then never be sure that the stand will stay up? One of the good points of the many on a Rudge is its stand; it invariably springs up with a welcome click as soon as the machine is wheeled off it, and once up it stays up until its rider decides otherwise. It also complies fairly well with the first two points raised—at any rate, I have ridden a Rudge for two years now, and have never had the machine topple over of its own accord. The only attention this stand ever had was a drop of oil on its pivots now and again.

Point 4 will require a bit of careful designing to carry out, but that such a device would be a great boon nobody will deny. The only way at present to get a really heavy machine on its stand is to get fairly and squarely behind it, place both feet on the stand and crossbar, and use man power. While doing this the 'bus will do its best to fall over, or, just as the weight is being brought past the dead centre, flop round will swing the front wheel, and if near a wall or near other machines will scrape its control levers or horn, or entangle them on those of an adjacent 'bus. It is really a two-man job to get a heavyweight on to its stand with the certainty of doing so without damage.

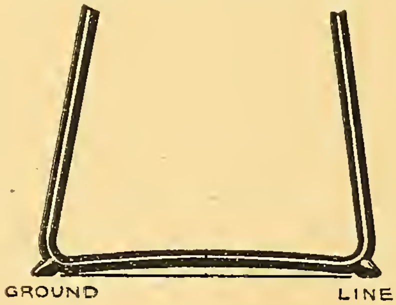

Fig. 2.

The Rudge stand—a desirable type which springs into place on wheeling the machine off the stand.

We are told that a heavy car can have all its four wheels lifted clear off the ground in seven seconds by merely turning a small handle. Why not some such device on motor cycles? The end of the handle-shaft could be brought up level with the top of the carrier, and a neat bevel or worm box housed at the bottom end of one of the rear stays.

A suitable link would then connect the cross-shaft of the bevel or worm gear with one leg of the stand so that a few turns of the handle would swing the stand up or down, according to the way the handle was turned.

A fitting of this sort would comply, of course, with point 3, with the exception that the raising of the stand would not necessarily be automatic, though a free-wheel device and spring could possibly be worked in so as to bring the stand automatically to the horizontal position as soon as it had been wound up sufficiently to transfer the weight on to the back wheel of the machine.

Occasional Comments

by IXION

Riding on Rations.

IT is a merciful providence, as the parsons say, that ordinary motoring is suspended. After a day in a factory or an office, one can make shift with a shepherd's pie, or a wee fillet of fish, or an egg with cheese grated over it, the whole washed down by Government ale. But just try war rations after a hundred mile spin over the downs on a fast jigger, when there is a bit of a nip in the air. Nothing but a couple of pounds of steak and a large tankard of Bass can meet the occasion. Unlimited motoring on limited rations would have spelt red revolution within a fortnight. Sometimes I am compelled to motor on national duties. On such trips I always carry a large turbot or a pen of Rhode Island Reds in full lay on the carrier. Even these precautions fail to satisfy my road appetite, so that I gaze at plump flappers with a cannibalistic gleam in my hungry eye.

The Conversion of a Nation.

SO far I have held my peace in the controversy as to whether my proprietors are justified in preparing for a German trade boycott after the war. The matter strikes me thuswise. It is folly to distinguish between the German Government and the German people until the Government is disowned by the people. It is equally folly to distinguish between the German army and the German nation, for the army *is* the nation, and has been so for many long years: this in a very special sense, seeing that German women are as a class quite extraordinarily docile, and subject to their husbands. My definition of our war aims is that we are fighting for the conversion of the German nation: civilisation will not be safe until a radical transformation of the German national character and ideals is evident. It is very doubtful whether the war will effect this: war may begin it, but the aftermath of the war, and a slow aftermath at that, may be left to complete it. Germany possesses extraordinary trading genius. She cannot invent, but she can copy and improve, she can manufacture scientifically and economically, and she knows better than any other nation how to extend her own trade, and to capture the trade of her competitors. If she be granted free trade before she is converted, she will become colossally rich within a very few years of the signing of peace. She would, if unconverted, employ her wealth to prepare another war. This next war would very possibly be cheap and rapid, and decided largely by a surprise attack from the air. That is a risk to which civilisation shall not be subjected with my consent: and therefore I am a whole-hogging anti-German until such time as unmistakable proofs of the conversion of Germany are offered me. If I had a pet tiger cub which had manifested a fancy for human blood, I would keep it caged until irrefragable evidence proved that I could safely loose it again.

The Camera and Bumps.

W. G. ASTON showed me some months ago several interesting photographic records of spring efficiency which he had taken, and as an American engineer reports similar experiments, the embargo on publicity is now removed. Mr. Aston attached small electric lamps to various parts of a car, and photographed it being driven over prepared bumpy surfaces by night. The resultant print consisted of a dark background crossed from side to side by a number of wavy white lines, which showed the height of each bump and the periodicity of each wave. Incidentally, by attaching lamps to various parts of the car, it was possible to tell what contribution was made to the net total insulation by the tyres, the springs, the rubber buffers between frame and body, the upholstery, and even the passengers' seats, and also to decide whether the front seats were really better sprung than the back seats, not to speak of whether a fat man motors more smoothly than a lean one. Here is a magnificent opportunity for the A.C.U. When the war is over, friend—or should I rather say "Major"?—Loughborough should organise *instanter* a trial of motor cycle front forks and rear springing. It can easily be arranged to cover a great variety of rough surfaces, a full range of speeds, and all loads from the minimum to the maximum. The eternal problem of motor cycling may then be solved, which, of course, is whether the X —— fork is an unspeakable dud or a brilliant invention.

What Hope for our Roads?

THE above suggestion is the more opportune as our roads have probably gone west for my lifetime at any rate. Various credulous optimists suggest that umpteen millions will be available for road expenditure as soon as peace is signed, but these fatuous gentlemen are crassly unaware of the tickets which sundry politicians from labour upwards (or downwards?) then intend to produce, and of the millions involved in these often visionary schemes. My own idea is that funds may just be available, if we get a decent peace, to repair our war-worn highways to some semblance of their former selves, whereupon a vastly increased motor 'bus and lorry traffic will immediately corrugate them afresh. More efficient forks and universal rear springing are essential to my dreams, and I look to the A.C.U. and the Aston camera-graph to co-operate in that noble work.

TWELVE MONTHS WITH A JUNIOR TRIUMPH.

A Cornishman's Experiences with a Two-stroke in his Home Country.

THIS short contribution is not intended to lay a thick veneer on a 2¼ h.p. Triumph, it is rather to be a fair description of a novice's first attempt at motor cycling—including its vexation and its happiness.

My first essay at motoring was the humble Auto-wheel fixed to a Gamage cycle, which combination I rode several months. An attack of rheumatic fever compelled me to give up severe exertion, which was imperative with an Auto-wheel round these parts, and I had to look for another mount. I decided on a two-stroke Baby Triumph.

My first ride was a succession of nervous fears; every stone seemed to come straight for me, pot-holes seemed endless, and to get from the side of the road to the higher middle a nightmare.

This state soon passed, and the joy of speed was upon me. I thought, "No more push-cycling for me."

A fortnight after this I began to take an interest in the mechanical side of my mount. I wondered how the explosions occurred in the crank case. I had been told quite seriously by a motor cyclist of some years' standing that to two-stroke meant that one charge was fired in the cylinder and the other in the crank case. But I could only see one plug. This made me think for myself. I soon decided that what really happened was that, although the mixture was drawn into the crank case, it was not fired there but in the cylinder. "But how?" I asked myself. I then took off the cylinders, and the situation was revealed to me, *i.e.*, the transfer port.

The author with the 2¼ h.p. Baby Triumph on which he gained his first knowledge of two-strokes.

A letter to the Editor of *The Motor Cycle*, with a stamped envelope for reply, confirmed my idea.

The Mystery of "Timing."

Ignition next claimed my attention. "Why did the spark occur at the right time, etc.?" I enquired, and was told it was due to "timing," and it was carefully impressed on me never to interfere with my magneto. However, I heard the chain rattle one day, and I took it off to tighten it. It was too badly stretched, so I bought a new one. How to get the timing right was the next thing.

Out came the Triumph booklet, and I read that by placing the arrow on the flywheel dead upright, and the piston at the top of its stroke, with the magneto control fully retarded and the platinum points just breaking, the spark would jump across this gap at the proper time. I carefully carried out the instructions, and, replacing the chain case, wheeled the machine on t the road, and, hurrah! it fired.

Petrol Consumption.

Some days afterwards, on comparing my mileag with the petrol consumption, I was surprised to fin I was getting only sixty-four miles to the gallon. Th only things, as a novice, to which I could attribut this poor result were a badly slipping belt and leakin tank. I carefully checked these things, and to m idea they seemed quite all right. Well, then, it mus be the carburetter. Taking off the lid of the floa chamber, I discovered the needle had worn badly. I therefore procured another one and fitted it.

Things were a littl better, but not much so off went anothe letter to the Edito with the stampe addressed envelope fo reply, and he suggested lowering th petrol level. I carefully examined the je and taking out th needle from the floa chamber. I gentl tapped the collar upwards. On giving th machine another tria I found I could ge 98 miles to the gallo of petrol. Not quit satisfied with this tota I had recourse t other methods. bought a quart o Prices' Huile de Luxe, tried one pint of paraffi to the gallon of petrol, used full air, instead of ai lever close to the throttle as previously, and found had more power and could get 103 miles to the gallon Beyond this total I could not get.

The First Tour.

I now had enough confidence to start on my firs tour, and, like most novices, to me it was anothe "milestone." Starting from Penzance my route la through Redruth, St. Columb, Wadebridge, to Tintagel, with a slight deviation to visit Newquay. Thi town is a rising watering place.

Arthurian Legends.

To resume, most people will have read or hear about the legends of Tintagel as told in Tennyson' "Idylls of the King," and of which there is muc supporting evidence. King Arthur and his knight built a castle here, and there are still several ruine walls standing on an island. About the centre of th island is a small roofless chapel, with rude stone seat and a slab of stone as the altar. Services are still hel once yearly.

welve Months with a Junior Triumph.—

Leading down to the sea stone steps were cut into he rock which are supposed to have been made as an mergency exit in case a besieging force became too nterprising. A drawbridge used to connect up with he mainland, and the roaring sea beneath made it lmost impossible for foes to get across. On the nainland side of the bridge is "My Lady's Bower." t is composed of very thick walls with small peepholes and windows all facing seawards. What appened to the ladies when the enemy appeared is ot mentioned, but presumably they, too, were withdrawn to the island fortress.

Battle Fields.

In the village of Tintagel there still remain some xquisite examples of Saxon architecture more or less n decay, but generally incorporated with a more nodern building. A large hotel now faces the Atlantic, and has taken off the romance of Tintagel omewhat.

The next stage is Launceston, through Camelford. On the way the site of the battle between King Arthur nd his traitorous nephew, Modred, at Slaughter Bridge, A.D. 543, is passed. In places it is rough going, hilly, etc., and the roads are badly cut up by he traction engines hauling timber. After visiting the church—which, by the way, is beautifully carved—also he ruins of the Norman castle, the front wheel is urned homewards through Bodmin and Truro. At he former place a most bloody battle was fought luring the civil war, and many minor engagements vere fought on the moors.

There is nothing of importance to be seen at Truro xcept the cathedral, which is a modern structure. From the market-place the left turning is taken, and after some bad hills have been negotiated Helston is reached.

The most noteworthy happening here is Flora Day, held annually on the 8th of May. All the lads and lassies dress themselves in flowers and dance in and out of the houses. From Helston to the Lizard is eleven miles over a good road.

(Top) A Cornish scene. Ancient stone crosses such as shown are found in all parts of the county.
(Bottom) The "First and Last" refreshment house at Land's End.

Serpentine Stone.

When so near Kynance Cove a point should be made of visiting it. Here the local stone known as Serpentine stands out of the sea in most curious forms, and the colouring is so beautiful that it well repays the little trouble walking down to it. I now turn back through Helston and Breage to Marazion, where the best view of St. Michael's Mount is obtained. It can be visited at low tide.

From Marazion to Penzance is three miles, and the whole of the journey approximately 225 miles.

Many such trips were taken on the 2¼ h.p. Triumph, which, beyond a little overheating one very hot day, gave very little trouble.

Writing on overheating reminds me how a good Samaritan (?) came to my aid. I was letting the engine cool down a bit when he passed me on a powerful combination. On seeing me walking the machine about with the exhaust lifted, he stopped and came back to see what was the matter. I was just in the act of putting the stand down, the spring mudguard being rather tight, when he said, "Allow me," at the same time giving a savage kick which smashed off the stand completely. He turned round, started up his own outfit, and was gone. That is the last I saw, or wanted to see, of that Samaritan.

During the twelve months my total mileage was 2,300, and expenses £12 9s. 1d., composed of items as follows:

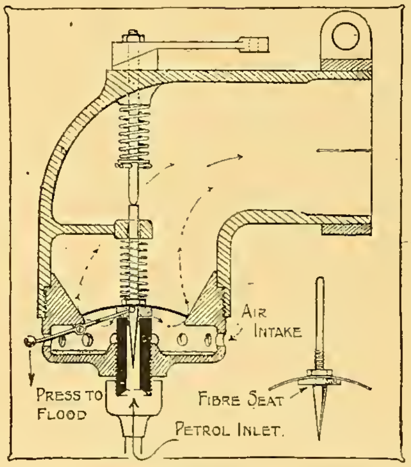
Petrol	£4	0	0
Oil		10	0
Accessories and repairs	6	4	1
Licences, including two petrol permits ...	1	15	0
	£12	9	1

The item accessories and repairs may seem rather high, but it includes a new tyre, belt, chains, piston rings, etc. Against this can be put down no loss through depreciation, as, having had constant renewals, I was able to sell the machine for the same as I gave for it. W.H.L.

THE MACHINE FOR THE MULTITUDE

Some Notes on the Post-war Market, and a Suggested Simple Carburetter Design.

THERE is no doubt that, when things have become normal, a great effort will be made to provide a motor cycle for the multitude, and keen will be the competition among manufacturers of cheap and inexpensive machines. Naturally, we look to the light two-stroke to satisfy the bulk of this demand. It is the only efficient type of mount which can be sold at a popular price without serious detriment to its efficiency. We have, in the past, seen various efforts to produce a cheap 3½ h.p. single-cylinder machine, and the less said about these efforts the better. The two-stroke is essentially the mount for the multitude, and there is no particular reason to conclude that it will necessarily retain its present diminutive dimensions.



A carburetter designed by "Chinook." The main feature is its simplicity, which will enable it to be produced cheaply.

Most of the small two-strokes at present on the market are very sturdy pullers, and do not overheat when abused. I have heard of remarkably good results having been obtained with these little machines fitted with light sidecars, and could quote numerous long and fairly arduous tours that have been thus completed, the machines having a two-speed gear, of course. Realising the possibilities in this direction, one or two firms are going all out for the featherweight sidecar outfit after the war, and this with perfect confidence as to the results they will achieve. All they are at present looking for is a lightweight three-speed gear box, which will doubtless make its *début* in due course.

To most riders of long experience the two-stroke in itself is an affliction, to say nothing of a two-stroke with sidecar attached, yet I myself am very sanguine as to the future of the lightweight outfit. The two-stroke engine behaves better under adversity in the way of overloading than any four-stroke.

Towing a Big Twin.

I well recollect on one occasion towing a 7 h.p. twin and sidecar for miles with a little Velocette, which, naturally, was run on low gear all the way, and which showed not the slightest tendency to overheat, whereas I have, on more occasions than one, caused much larger four-strokes to overheat in two or three miles under similar conditions. Also it must be borne in mind that the multitude is no connoisseur; so long as a machine will rev. itself out into the country and carry two rather further and faster than pedal-cycles, so long as it will climb anything within reason on its low gear, and can be depended upon for getting there and back without trouble, and, above all, so long as it is cheap, the multitude will throng to purchase it.

As for the certainty of a good market, almost every soldier who comes home on leave is determined to possess a motor cycle after the war, while thousands of munition workers have money laid by for that purpose. Wise is the firm that has its after-war campaign clearly cut and dried.

Simplicity Essential.

Hitherto no genuine effort has been made to produce a machine of absolute simplicity. The magneto is, of course, inevitably a costly instrument, and it would be unwise to attempt economy here. A lightweight three-speed gear box might be quite easily produced, and there is no reason whatever why a high-priced instrument in the present-day carburetter should be used.

Here, indeed, is unlimited scope for the inventive genius. There is no doubt whatever that a perfectly good and efficient carburetter could be made for 8s. or 10s., and such an instrument, after the war, would sell by the thousand. There is no reason why a carburetter should have more than one accurately machined part, such as, for example, the suggested design on this page. It consists merely of a tapered needle accurately machined to fit its jet, and held down thereupon by its own weight and a light hair spring—a fibre collar being fitted to take the hammering effect and provide a petrol-tight joint. Mounted on this needle is a thin aluminium mushroom, past which the total air supply is drawn, so that the suction of the engine tends forcibly to lift the tapered needle from its seating. The higher it is raised the more petrol is allowed to pass the jet, and the more air is allowed to pass the mushroom, so that the working could be (if desired) perfectly automatic. Control is effected in the simple manner shown by determining the amount of lift possible for the reciprocating needle.

I do not hold up this arrangement as ideal, as each designer has his own ideas, but merely as illustrating the simplicity possible in the case of one single fitment for the machine for the multitude—no float chamber, no pistons or barrels, and the very simplest type of control mechanism. Several different sizes of needles with or without discs could be stocked, of course.

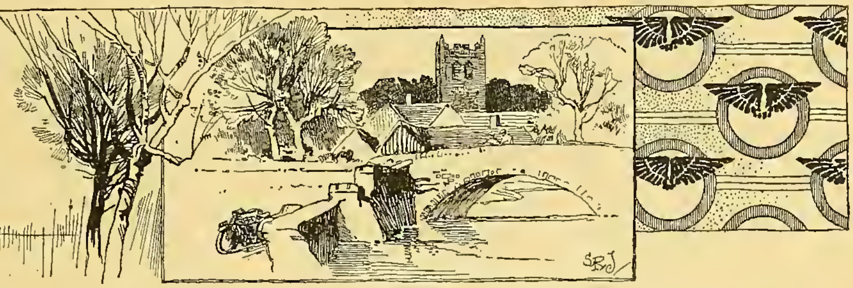
THE BICYCLIST'S EQUILIBRIUM.



A Short Discussion on the Various Forces which cause a Motor Cycle to continue in its Course. By "Mohandis."

WHEN I innocently chose the steering of a bicycle as an example of centrifugal force in my recent articles on "Mechanics," I had no idea that I should tap such a stream of correspondence. Many of the letters have been extremely helpful, while some opinions were clearly unsound; but, as the advantage of the Correspondence column is that neither the Editor nor his contributors are to be held responsible for the views expressed therein, I have not thought it necessary to question statements with which I could not agree. There has recently appeared an article on the subject of bicycle balancing, however, which does seem to call for some comment; I refer to Mr. W. Arthur Jones's remarks on "The Dynamics of Bicycle Locomotion" in the issue of January 31st. As far as I can gather, the gist of this article seems to be that, whereas a bicycle at rest is in a condition of unstable equilibrium, yet as soon as the machine begins to move it instantly acquires some mysterious kind of "inherent stability." Whether intentionally or not, I cannot say, but the writer certainly gives the impression that the rider is not called upon to take any part whatever in the control of the machine—all he has to do is to trust to its "dynamic equilibrium." The obvious inference is that a sack of potatoes could ride a bicycle just as easily as a human being.

Gravity and the Straight Path.

Mr. Jones makes no attempt to explain what, after all, is the core of the matter; that is, how it is that the cyclist is able to frustrate the ceaseless efforts of gravitation to bring him to earth. That is the problem which is always so puzzling to the uninitiated, and which it is the purpose of the present discussion to solve. The explanations that have so far been offered are (1) centrifugal force, (2) "shifting the point of support," and (3) gyroscopic action. But Mr. Jones categorically sweeps all these on one side, and asserts, in effect, that the bicycle just balances itself. Should it depart from its straight path by even an infinitesimal amount, an infinitely great force comes into operation to push it back into the ways of righteousness. The fatal flaw in this argument is that the one thing a bicycle will *not* do is to travel in a straight path; for, if the cyclist's equilibrium is once disturbed (and it is in a state of constant disturbance), his only hope of regaining his balance is by temporarily *abandoning* a straight course. Otherwise why should he require to give incessant impulses to the handle-bar?

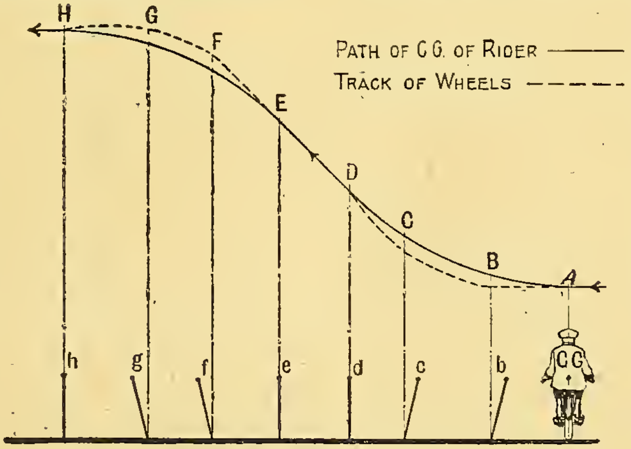


Fig. 1.—Diagram of an exaggerated "wobble," showing how a cyclist loses and regains his equilibrium. The upper curves represent the cause of the operation in plan, while the lines beneath show the rider's inclination to the vertical at various stages.

Cornering.

As for the opinions on cornering expressed in the article in question, they are frankly beyond me. I have absorbed a reasonable quantity of rigid dynamics—that "very difficult subject"—in my time, but when I read of "forces peculiar to the bicycle," and of centrifugal force only increasing the banking "slightly," I can only conclude that I must have studied a different brand of rigid dynamics from that favoured by Mr. Jones. My own views on cornering agree absolutely with those of a correspondent signing himself, very aptly, "Mathematician" (January 24th). In the original articles on "Mechanics" I was under a sort of self-denying ordinance to eschew the use of mathematical symbols, otherwise my explanation of cornering would probably have forestalled this correspondent's almost word for word. While here expressing my especial thanks to "Mathematician," I should like to refer particularly to the last paragraph of his letter. The point here raised, that centrifugal force is really a sort of inertia, is one that I endeavoured to lay special stress on in the third instalment of the "Mechanics" series. Inertia, in the ordinary sense of the term, is the resistance that a body offers when *linear* acceleration is impressed upon it; centrifugal force is the resistance—a reaction of precisely the same nature—that the body offers when *radial* acceleration is impressed upon it.

Before proceeding to make a few further obser-

The Bicyclist's Equilibrium.—

vations on the subject of the cyclist's equilibrium, perhaps I ought to say that I am sorry if, through ignorance or dulness of comprehension, I have done Mr. Jones injustice; but as at present his article appears to me to be misleading, I thought it necessary to dissociate myself from his opinions in the way I have done. Now the starting point of any discussion on the theory of the stability of single track vehicles must be the fact, which no one except Mr. Jones has questioned, that such a vehicle invariably progresses in a series of more or less pronounced curves or wobbles. Let us, therefore, endeavour to trace the life history of a wobble, and for the sake of clearness we will consider a well-developed specimen, such as would be generated by a learner in the art of balancing. The accompanying sketch is an attempt to represent the state of affairs at different stages of the proceedings. The upper curves show, in *plan*, the paths taken by the rider's centre of gravity and by the wheels; while the lines beneath are intended to be *rear* views of the cyclist. At point A we will assume that the learner has momentarily succeeded in maintaining his equilibrium; he will therefore appear to an observer stationed in the rear to be upright, as shown in the small view below A. As the bicycle proceeds from A to B, however, it begins to gravitate towards the right, and as the rider is too inexperienced to apply at once the necessary correcting impulse, he finds himself at B with quite a considerable list to starboard, as indicated by the sloping line *b*. Realising at this stage that prompt action is called for to avert a spill, he turns the handle-bar so as to steer to the right, with the result that the arc BC is traversed. Although this manœuvre, by calling into play centrifugal force to neutralise the effect of gravity, has prevented any further declination from the vertical, the rider has still to regain his vertical position. Accordingly, at C, he turns the handle-bar still more, thus reducing the radius of the arc along which the cycle is travelling. The influence of gravity acting through *c* now becomes insufficient to impress on the rider the increased radial acceleration necessary to make him traverse the smaller circle—*i.e.*, centrifugal force overcomes gravity, and the machine rights itself, as at D.

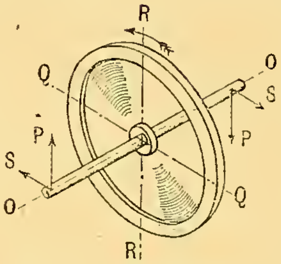

Fig. 2.—Illustrating the principle of gyroscopic action Owing to the effect of precession, the forces P P cause the ends of the spindle to move in directions S S.

Direction.

The learner has now regained his equilibrium, but he has lost his direction, for he finds himself heading along the line DE for the ditch at the side of the road. A further series of operations, as shown at F, G, and H, is therefore required before he once more resumes his original course. Now I do not pretend for a moment that my sketch is anything but a diagram of a diagram, so to speak. For one thing, the two wheels do not follow the same track, as I have shown them to do. Actually, of course, the back wheel always "cuts off the corners," and thus very definitely assists in bringing the points of support under the centre of gravity. Also, needless to say, the actual course of a wobble is not such a smooth and well-conducted business as is indicated in the diagram. Still, the rider's c.g. has unquestionably travelled in a curved path, and therefore centrifugal force has infallibly come into play. It is really only a question of terminology as to whether centrifugal force or "shifting the point of support" plays the greater part in balancing. The rider has undeniably regained his balance at D by steering in such a manner as to bring his point of support beneath him, but he could not have done so without the aid of centrifugal force. On the other hand, as a correspondent, "Allied," has shown in his letter of January 24th, that a bicycle can be balanced without the aid of centrifugal force, provided that special arrangements are made. To quote again from my good friend "Mathematician," centrifugal force is merely "a measure of the tendency of a body to refuse to move in a circle"; if there were no such tendency it would be futile for our learner to steer in a sharper circle at C in the figure.

Gyroscopic Action.

The part taken by gyroscopic action in balancing a bicycle at high speeds is so interesting that a little further explanation of the matter may not be out of place. The accompanying figure will give an idea of the principles involved. The wheel shown is imagined to be revolving rapidly about the axis OO. If vertical forces PP are applied to the ends of the spindle it would naturally be expected that the wheel would tend to tilt about the horizontal axis QQ, but what actually happens is that the tilting takes place about the *vertical* axis RR. In other words, the ends of the axle move horizontally in the direction of the arrows SS. This is the phenomenon known to physicists as "precession," and it is the fundamental principle embodied in all types of stabilising apparatus which employ the gyroscope. Examples of its action are very common—there is that popular toy, the gyroscopic top; then we have the motion of an ordinary peg-top; the earth also is subject to "precession," hence the astronomical term, "precession of the equinoxes"; but the most striking instance for our present purpose is that mentioned by a correspondent "G.R.B." If a cycle wheel be spun as shown in the figure, and the couple PP be applied to the spindle, the spindle will manifest a violent disinclination to follow the direction of the forces, but it will instead whip round horizontally.

Now the interesting point is this: if the cycle wheel be revolving along the road instead of between the rider's fingers, the effect of precession is to influence the steering in precisely the manner required to balance the bicycle. Thus, if the cycle heels over to the right, this will bring forces to bear on the wheel spindles exactly corresponding to the forces P P in the diagram. Consequently both wheels will tend to veer round to the right, as indicated by the arrows S S. The front wheel, being free in the steering column, is quite able to obey this impulse. Further, all bicycles are constructed in such a way that a right hand couple applied to any part of the machine causes the front wheel to swivel to the right. (This is easily demonstrable:

80 Generals and Admirals!

Impressive Facts about "Pelmanism."

THE remarkable extent to which the new movement—Pelmanism—is being adopted by officers and men affords impressive reading.

There could, indeed, be no finer or more convincing evidence of its intensely *practical* value than the fact that over 20,000 British officers and men (Naval and Military) are studying it whilst on active service. This includes 80 Generals and Admirals! All correspondence being confidential, no names can, of course, be published.

From time to time the announcements made by the Pelman Institute have included some of the more interesting letters from officers at the Front or with the Grand Fleet, giving more or less precise particulars of the direct benefits accruing to them from the adoption of Pelman principles. Promotion, distinction, increased efficiency, a keener zest for work: self-confidence, individuality, judgment, decision: a perfect memory (most valuable of qualities in this super-scientific war), concentration—these are some of the benefits daily recorded. Small wonder that a distinguished General writes that "the value of the Pelman Course can hardly be exaggerated." His letter, with others of special interest, will be found below.

Business and professional men are equally appreciative. The benefits of Pelmanism are so clearly apparent (and so invariable) that scepticism and prejudice have vanished. The facts recorded, *by students of the Course themselves*, dispose of all doubt or question as to the value of "Pelmanism."

If there is a reader of *The Motor Cycle* who has not yet received a copy of *Mind and Memory*, in which the principles of Pelmanism are explained at length, and in which a full synopsis of the Course is given, he (or she) should write for this *brochure* to-day. It will be sent, *gratis and* post free, together with a full reprint of *Truth's* outspoken report on the work of the Pelman Institute, upon application to the address given at the foot of this page.

A Distinguished General's Verdict.

One of the most emphatic endorsements that the Pelman Course has ever received comes from a distinguished General with the B.E.F. He says:

> **"The value of the Pelman Course can hardly be exaggerated. I agree it should be nationalised."**

Following upon the remarkable letters recently published, in which Colonels, Majors, and Captains (both Army and Navy) have attributed their promotion, *and, in some cases, their distinctions*, to Pelmanism, the General's pronouncement is of special significance.

For the benefit of those readers of *The Motor Cycle* who have not already seen the letters referred to, they are reprinted here.

"The Unsoldierlike Sub."

The first is from a Captain with the B.E.F. We give his letter in its entirety:

> "I should like to call your attention to the facts of the story of my Pelman Course.
>
> "When I began I was looked upon with disfavour by the C.O. of my battalion at home as being a sleepy, forgetful, and unsoldierlike sub. When I began your Course my star began to rise—I had the ability, but had not been able to use it. I left the home battalion with my C.O.'s recommendation as being the best officer he had had for more than a year, and came to France.
>
> "I was then appointed as a second lieutenant to command a company over the heads of four men with two 'pips,' and have now three stars and an M.C.
>
> "That I was able to make use of my abilities so successfully I attribute entirely to the Pelman System."

That his is not by any means an isolated case is shown by the next letter, which is remarkable for its brevity. It is also from a Captain, who, in response to the question, "What have you gained from Pelmanism?" replied:

> **"Three Stars,**
> **A Military Cross, and**
> **A Clearer Head."**

Another officer suggests that the announcements made by the Pelman Institute err on the side of modesty. He writes:

> "One great point in favour of your System which, if I may say so, you do not make enough of in your advertisements is the cumulative benefit accruing.
>
> "As far as I can see, once having got on the right track and rigidly following the System, there should be no limit to the ultimate mental capacity obtained."

Each letter supplies its own adequate comment. Take the epistle of a Lieutenant-Colonel, who, writing from Salonika, says:

> **"As a direct consequence of Lesson Two I have got a step in rank."**

Similarly, a Major attributes his promotion *and his D.S.O.* to Pelmanism; the Captain of a fine cruiser thanks Pelmanism for his command, having been promoted by selection over the heads of senior officers!

There is, in fact, a bewildering mass of direct personal testimony to the value of the Course from every rank and from every unit of the British Army and Navy.

It is not always promotion that is the object of those who take up the Pelman Course. Here is a letter which presents another phase:

> "The Course has prevented my becoming slack and stagnating during my Army life—this is a most virulent danger, I may add. It inculcates a clean, thorough, courageous method of playing the game of Life—admirably suited to the English temperament, and should prove *moral* salvation to many a business man. 'Success,' too, would follow—but I consider this as secondary."

Easily Followed by Post.

To the uninitiated it may well appear impossible that such remarkable results can be attained in a short time as a consequence of half an hour a day for a few weeks spent in studying lessons. Yet it is the bare truth, and it should help readers to realise what a tremendous force for personal betterment "Pelmanism" is.

As a reader of the Course recently wrote: "If people only knew, the doors of the Pelman Institute would be literally besieged by eager applicants."

Following the intensely interesting lessons and exercises the students of Pelmanism rapidly develop a brilliant Memory, strong Will Power, complete power of Concentration, Quick Decision, Sound Judgment, an ability to Reason clearly, to Converse attractively, to Organise and Manage, and to conduct their work and social duties with Tact, Courage, Self-confidence, and Success. All mental weaknesses and defects are, on the other hand, eliminated—such as Mind-wandering, Forgetfulness, Weak Will, Aimlessness, Bashfulness, Self-consciousness, the "Worry Habit," etc.

Over 250,000 Men and Women.

The Pelman Course has already been followed by over 250,000 men and women. **It is directed through the post, and is simple to follow.** It takes up very little time. It involves no hard study. It can be practised anywhere, in the trenches, in the office, in the train, in spare minutes during the day. And yet in quite a short time it has the effect of developing the mind just as physical exercise develops the muscles, of increasing your personal efficiency, and thus doubling your all-round capacity and income-earning power.

A full description of the Pelman Course is given in *Mind and Memory*, a free copy of which (together with *Truth's* special supplement on "Pelmanism") will be sent post free to all readers of *The Motor Cycle* who send a postcard to The Pelman Institute, 199, Wenham House, Bloomsbury Street, London, W.C.1.

B·L·I·C

The British-built Magneto with a record behind it.

RENOWNED for Reliability and Efficiency, its performances under war conditions have served to perfect the sterling qualities of the "B.L.I.C." MAGNETO, and to-day it stands supreme amongst magnetos—whether British or foreign.

London, W.1.
Proprietors - VICKERS, LIMITED.

The Bicyclist's Equilibrium.—

stand at the right-hand side of your machine; push the saddle away from you with your left hand, and pull the top tube towards you with the other hand; the front wheel immediately swings round to the right.) We see, then, that the couple induced in the back wheel by the effect of precession also does its share in turning the front wheel to the right. In brief, if the bicycle tends to fall to one side or the other, gyroscopic action comes into play and tends to turn the handle-bar in a direction which will enable centrifugal force to right the machine *in just the same manner that the rider does.* The higher the speed, the greater the gyroscopic action, hence the smaller the effort required from the cyclist. In a motor cycle, of course, the engine flywheel adds its quota to the effect produced by the road wheels.

The Mind of the Rider.

There is just one other correspondent to whom I wish to refer, and that is "Top Heavy." I like the tone of his letters very much, and I should be sorry to leave him with the impression that he and I are at variance on any material point. Our little difference of opinion hinges solely on the question of what are, and what are not, to be considered as forces. When I was writing as the author of articles on mechanics, which is the science of strictly physical forces (among other things), I naturally had to rule out of account such things as mental and nervous forces; but now that I am trying to discuss the whole general question of the cyclist's equilibrium, I can cordially agree with the point of view expressed by "Top Heavy" in his letter of January 31st, viz., that it is the *mind* of the rider, and his personality generally, which is the controlling and the only really indispensable partner among the varied company of forces and influences that unite to keep him off the ground.

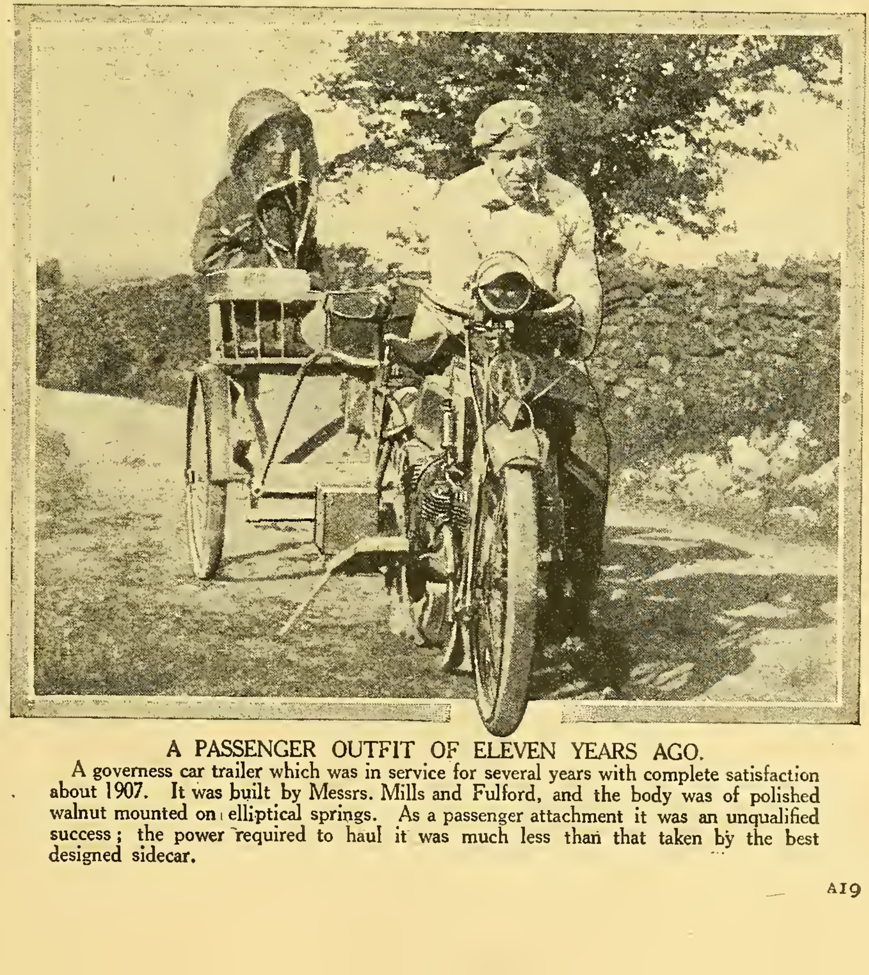
Although this article is intended to have the effect of oil on troubled waters, there is a possibility that it may have a contrary action, and serve instead as fuel for further controversial fires. It it does, I should like to make the following suggestion. This problem of the bicyclist's equilibrium is one that must have been threshed out scores and scores of times already. The publication of these researches would be of service, I think, to *The Motor Cycle* readers. [We propose to publish such conclusions in the near future.—Ed.]

ABOUT SPARKING PLUGS.

Does the Position of the Plug in the Cylinder affect the Power?

A READER is suffering from sparking plugs which automatically widen their sparking gap in use, and of one plug he states that in a single long run it will extend its gap so fast that towards the end of the run the spark can no longer jump the gap. I had better leave this question to the experts, but the plug in question must be uncommonly bad. Either the metal becomes partially fused at the tips of the electrodes so that their length actually is abbreviated, or else the electrodes wilt under the heat and the lower electrode droops away from the central point. The same correspondent advances a theory that on his two-stroke machine better combustion is obtained when a single gap sparking plug is so mounted that the gap is on the upper side of the plug, the plug being screwed into the side of the cylinder and not into the head. I find it difficult to believe that any appreciable difference in running could result from raising or lowering the spark position by a quarter of an inch in the cylinder; but I state the point in case any authority can settle it. I have never assured myself that a perceptible difference resulted from using a plug in the cylinder head or cylinder wall, and, if the latter, on the side adjacent to or remote from the inlet valve; but people who have conducted precise scientific experiments may be able to clinch the point.

ROAD RIDER.

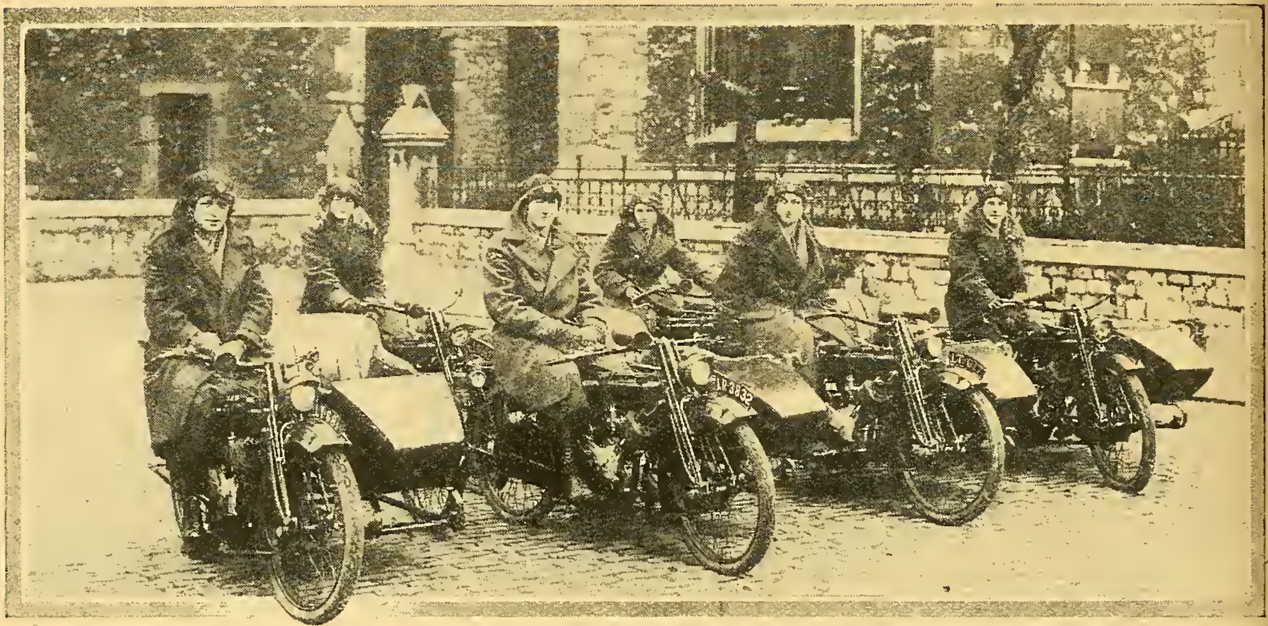


A PASSENGER OUTFIT OF ELEVEN YEARS AGO.

A governess car trailer which was in service for several years with complete satisfaction about 1907. It was built by Messrs. Mills and Fulford, and the body was of polished walnut mounted on elliptical springs. As a passenger attachment it was an unqualified success; the power required to haul it was much less than that taken by the best designed sidecar.

Lady Motor Cyclists in the British Army.

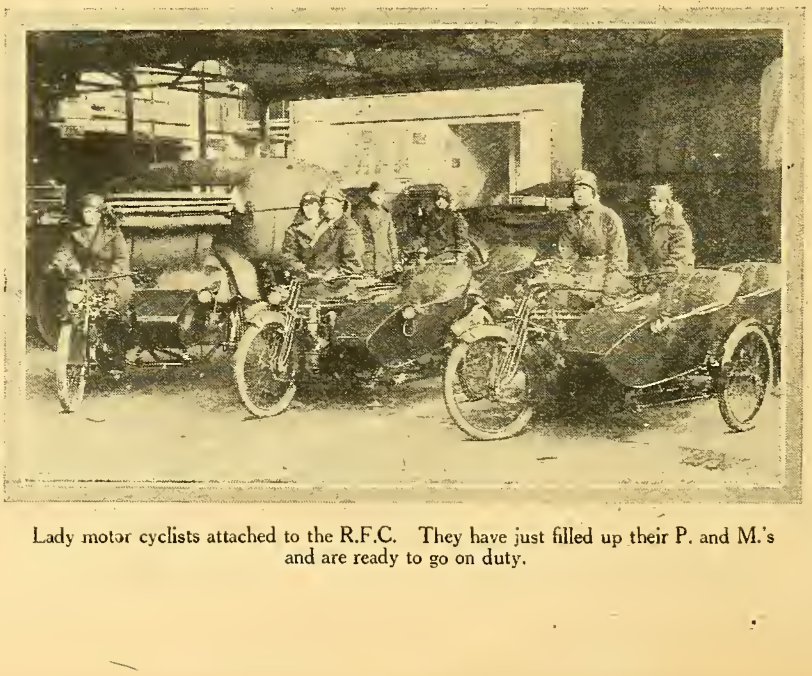
A Glimpse of the Work of one of the Sections of the Women's Legion.



A group of the R.F.C. lady motor cyclists.

MENTION of lady motor cyclist despatch riders attached to the British Army has been made from time to time in these pages. Thanks to the courtesy of the Transport Department of the Air Ministry and of the officials of the Women's Legion, we are able to reproduce some photographs showing a few of these women who are so contentedly doing men's work, and to record a few facts concerning their duties. The Women's Legion (Motor Drivers' Section), under the direction of the Commandant, Miss Christabel Ellis, O.B.E., accepts recruits for despatch riding for both the A.S.C. and R.F.C. Motor Transport Sections. A reference was made to this splendid body in the issue of the 28th ult., in which a letter from its president, Lady Londonderry, was quoted.

The section is under the direct control of the War Office (Q.M.G.3), which has compiled a complete set of regulations issued with Army Orders. Despatch riders on probation receive 25s. a week, and when duly qualified 35s. a week. After a month on probation they must sign on for twelve months or for the duration of the war. The hours are from 8 a.m. to 6 p.m., with one and a half hours for meals, and 5d. per hour is allowed for overtime. Stoppages from pay may be made for offences, such as careless or reckless driving, disobedience of orders, applying for sick leave without justification, or for damage to a vehicle caused by accident or neglect for which the driver is held responsible. It will be seen, therefore, that the lot of the lady despatch rider is not an easy one, but those we saw at a large R.F.C., M.T., depot looked particularly well and happy. They are entitled to week-end leave once a month, and to the usual public holidays if the exigencies of the Service permit.



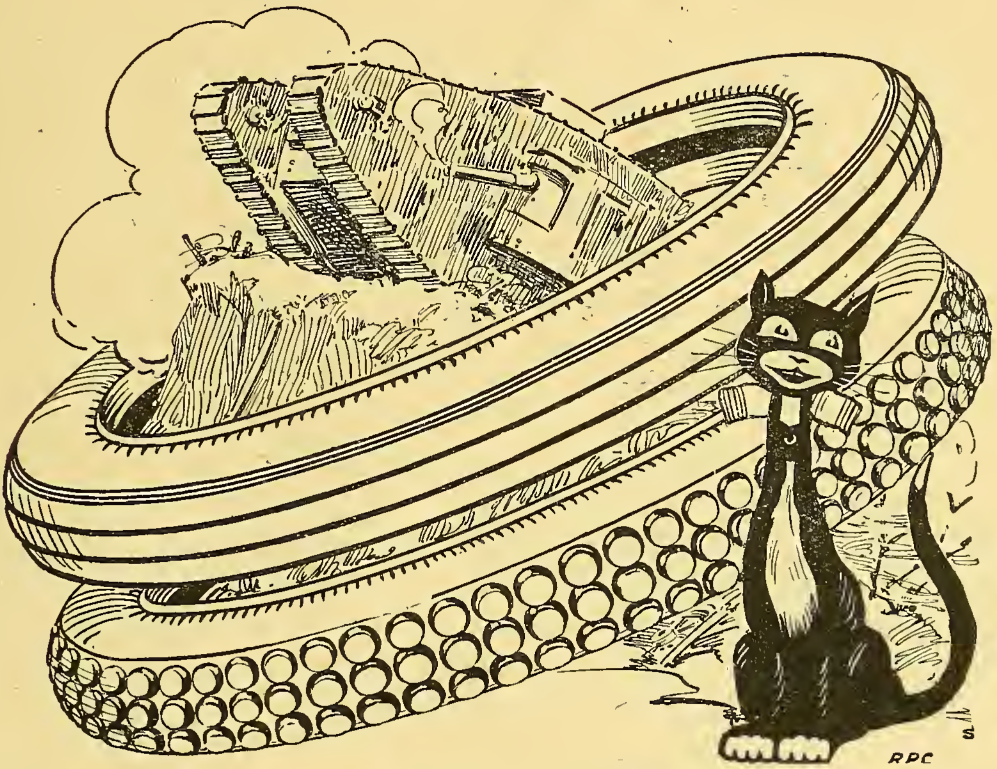
Lady motor cyclists attached to the R.F.C. They have just filled up their P. and M.'s and are ready to go on duty.

The Machines Used.

The girls use standard R.F.C. model P. and M. motor bicycles and sidecars, and have to clean their own engines, make small adjustments, and generally maintain the machines, but the mud is removed

HUTCHINSON

"The Tyres with NINE Lives"



STRENGTH and DURABILITY

Hutchinson Tyres, like the tanks, have been built for hard, gruelling service. The strength and durability of Hutchinson Tyres have established their supremacy "on active service," and their hard-wearing qualities are enabling the motor cyclist "at home" to practise the strictest economy in tyre maintenance. For long mileage at low mileage cost Hutchinsons have no equal.

HUTCHINSON TOURIST TROPHY TYRES

THREE-RIBBED OR RUBBER-STUDDED.

A copy of our 1918 Catalogue, containing full details, prices, etc., will be sent post free on request. Why not write for your copy TO-DAY?

HUTCHINSON TYRES,
70, Basinghall St., LONDON, E.C.2.

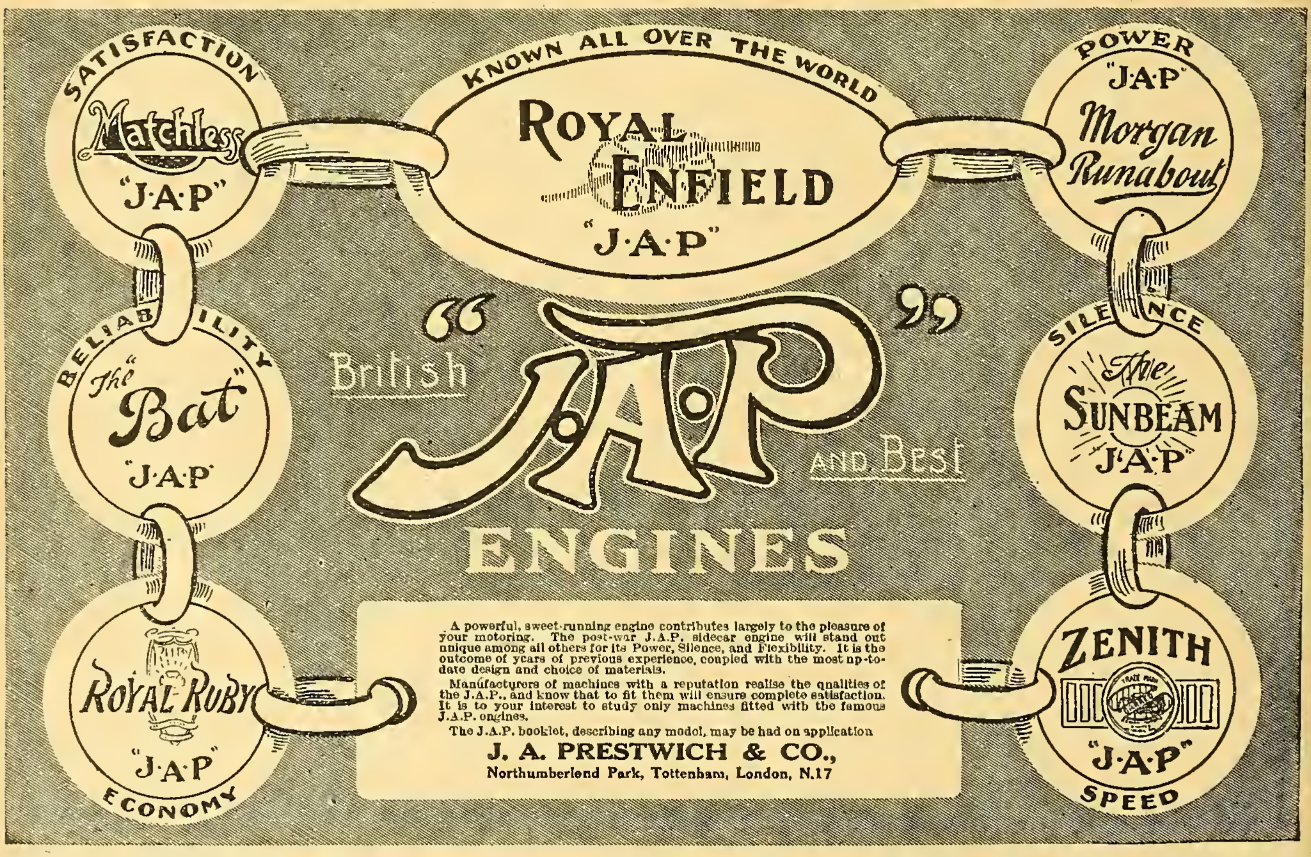
The use of this Badge is an indication that this Firm has been accepted as genuinely British by a tribunal of Trade Competitors.

AT the present time SUNBEAM MOTOR BICYCLES can only be supplied under a Ministry of Munitions permit, but the Makers have a waiting list for those who desire to possess them at the earliest possible moment when conditions begin to become normal.

Further particulars will be sent on application to ——————

John Marston, Limited, 11, Sunbeamland, Wolverhampton.

London: 57, Holborn Viaduct, E.C.1.
157 & 158, Sloane Street, S.W.1.



A powerful, sweet-running engine contributes largely to the pleasure of your motoring. The post-war J.A.P. sidecar engine will stand out unique among all others for its Power, Silence, and Flexibility. It is the outcome of years of previous experience, coupled with the most up-to-date design and choice of materials.

Manufacturers of machines with a reputation realise the qualities of the J.A.P., and know that to fit them will ensure complete satisfaction. It is to your interest to study only machines fitted with the famous J.A.P. engines.

The J.A.P. booklet, describing any model, may be had on application

J. A. PRESTWICH & CO.,
Northumberlend Park, Tottenham, London, N.17

Lady Motor Cyclists in the British Army.—

by mechanics. One of the ladies in the group qualified for the R.A.C. driving examination some six months ago, then took up ambulance work, applied for a post Overseas, but, as she was found to be medically unfit for work abroad, she then became an R.F.C. despatch rider, although she had never ridden a motor cycle before.

The lady despatch riders are engaged in short journeys only, chiefly in the Metropolitan area, and rarely go very long distances. One of them told us that the longest journey she had had was as far as Woking. Their usual uniform is that in which they are shown in the accompanying photographs, but in wet weather they are provided with oilskins and waterproof leggings. The lady car drivers are, of course, well protected from the elements, as their vehicles are provided with efficient hoods and screens, and we cannot but express the greatest admiration for the brave girls who carry on in their duties in all weathers and throughout the whole year with so small a protection as the average motor cycle affords.

OVERSEAS TRADE DEVELOPMENT.

A Scheme for the Motor Cycle Trade only following the Main Lines of Sir Charles Mandleberg's General Trade Scheme.

ONE of the most promising indications of the intention of British manufacturers to tackle seriously the problem of Overseas trade after the war was the meeting of some of the important men in the industry, recently held in Birmingham, at the invitation of the Sphinx Manufacturing Co., who acted as hosts on the occasion.

Briefly, the scheme submitted by Mr. H. G. Longford, a director of this company, was one providing for co-operative action, by a group of non-competitive firms in the motor cycle, tyres, and accessories sections of the industry, in the Overseas market, commencing with Canada as a field possessing very great potentialities. This is also a market that has not, up to the present, been cultivated to any serious extent by many manufacturers.

It is proposed that the firms joining in the scheme shall take steps as soon as practicable to develop business in Canada by the creation of a thoroughly well organised central depot in the Dominion: this central depot being the headquarters of the firms concerned, and providing ample showroom, office, and stores accommodation. A full stock of machines, accessories, and spare parts will be carried, and this, it seems to us, will go far towards overcoming one of the most serious complaints of our readers in the territory referred to, viz., the difficulty of obtaining adequate service, and especially spare parts, accessories, etc., at reasonable rates; this difficulty, of course, obtaining not merely in Canada, but practically in every other part of our Empire.

The Sales Organisation.

One assumes that from the central establishment there will be developed a really first-class sales organisation, employing "live" men capable of more than holding their own with their competitors; and, in passing, we would venture to suggest that there will be no room for any other than first-class, well-paid men, if the scheme is to be successful.

It is to be hoped that this central depot will not exist for the purpose of showing profits on its own account, as a distributing agency: its aim rather being to deliver goods through appointed agents to the consumer with the least possible addition to the retail prices obtaining in Great Britain.

Fixed retail prices throughout the Dominion, which must compare favourably with the home prices, together with an ample supply of spare parts and accessories, also sold at reasonable prices, are features which, if adopted, will enormously increase the selling possibilities of British machines.

After-the-War Methods.

There was never a time in the history of the movement when it was more definitely "up to" British manufacturers to convince motor cyclists at home and abroad that their after-the-war methods will meet the needs of the case, and so we welcome this suggestion of a practical step in that direction, and think it well to inform our readers—particularly those Overseas—of what it is proposed to do.

The meeting was adjourned for a month, in order to consider details; and it is requested that any manufacturers interested who were not present should communicate immediately with the Sphinx Manufacturing Co., who, it should be added, are not putting forward this scheme on their own account, but merely because it is necessary for one firm or another to take the first step.

COAL GAS FOR MOTOR VEHICLES.

WE have already stated that a prize of £1,000 has been offered by the Automobile Association and Motor Union for the best invention enabling coal gas to be used with advantage as a propellant of motor cars and motor cycles. The conditions which have now been published are framed with the idea of enabling motorists to carry sufficient gas in a small space not exceeding nineteen cubic feet, to provide the equivalent of between two and three gallons of petrol, and so ensure a possibility of running cars distances of approximately fifty miles on one charge of gas. The conditions are so drafted that the winner of the prize must place his invention at the disposal of the British motoring public on terms fair to himself and users.

Intending competitors may obtain copies of the entry form and conditions upon application to the Secretary of the Automobile Association and Motor Union, Fanum House, Whitcomb Street, London, W.C. The competition will close on the 31st of December, 1918. There is no entrance fee or charge of any description.

CURRENT CHAT

Time to Light Lamps

GREENWICH TIME.

Mar.	14th	6.30 p.m.
,,	16th	6.33 ,,
,,	18th	6.36 ,,
,,	20th	6.40 ,,

Prices of Petrol.

The retail price of petrol has fallen one halfpenny per gallon, No. 2 "War Spirit" now being obtainable in England and Wales at 3s. 5½d. per gallon, while No. 3 grade is sold at 3s. 5d. per gallon.

Magneto Production.

Nothing in connection with the motor industry since the outbreak of war is more significant, perhaps, than the way in which British manufacturers have risen to the occasion to produce magnetos to replace the supplies which formerly came from Germany.

Trading Possibilities in Uruguay.

According to an American motor cycle journal, there are some trading possibilities awaiting an enterprising firm in the South American Republics. J. H. Figuerra, Calle Magallanes, 1,070, Monte Video, Uruguay, South America, is asking for motor cycle catalogues to be sent to him, with a view to future business. Would any English firm care to answer his request, which, of course, is addressed to the American trade?

The German Intellect Again.

We cull the following from the *Birmingham Daily Post:*

"AMSTERDAM.

"A frontier correspondent of the *Telegraaf* reports that the Germans at Zeebrugge have adopted a new method for catching hostile airmen. Towards evening they send up twenty captive balloons without crews and attached to electrified steel cables. The electric barrier thus created constitues a great danger to all airmen coming into contact with it.

And here's the Plum!

"The Germans have also manufactured a new and improved type of aeroplane, fitted with three propellers, one being so arranged that it can keep the aeroplane for some time stationary above a certain point, thus permitting the bomb-thrower to aim with greater accuracy.—Reuter."

Licence Coupons for Motor Spirit.

The Motor Spirit Order issued by the Board of Trade informs licensed dealers that from and after March 1st they must not take delivery of any motor spirit from any person for the purpose of resale without handing to such person petrol licence vouchers representing the same number of gallons as are then delivered to him. The effect of the Order is merely to restrict the replenishment of a licensed dealer's motor spirit stock at the end of a month to the amount of his sales during that period.

A Tragedy.

A correspondent seeking information begins his letter, "Having bought a motor cycle which has been converted into gas . . ." Poor fellow! he has our sincerest sympathy!

Finances of the Motor Cycling Club.

The Motor Cycling Club has invested the balance of its funds—some £475—in War Loan. The activities of the club, of course, have been in abeyance since January, 1915, and members now pay the nominal subscription of 5s. per annum only, while those serving with the Colours pay no subscription at all.

Four Cylinders.

We understand that a number of British motor cycle firms are angling in four-cylinder waters. Several have models on paper only, but one or two have experimental machines on the road. Who will be the first boldly to acknowledge their conversion to this fascinating type? More than one of them have stated that, for sidecar work, the four-cylinder is it.

Maj. Chas. Jarrott, the one time famous racing motorist, was recently invested with the Order of the British Empire. In the very early days of motor cycling he rode a racing motor tricycle.

Special Features

THE BICYCLIST'S EQUILIBRIUM.

A MACHINE FOR THE MULTITUDE.

TWELVE MONTHS WITH A JUNIOR TRIUMPH.

£1,000 Prize.

The conditions relating to the prize offered by the A.A. and M.U. in connection with coal gas are now ready.

From Cairo to Jerusalem.

The Church Army Organiser has recently undertaken a motor bicycle ride from Cairo to Jerusalem.

Training of Disabled Soldiers.

At the request of the Ministry of Pensions, the Kent Education Committee has prepared a scheme for training disabled soldiers in professional, commercial, and industrial occupations.

£300 Petrol Penalty.

Judgment for £300 penalties for using petrol without a licence was given in the King's Bench by Mr. Justice Darling against Mr. E. W. Beeston, a Birmingham bookmaker. For the defence it was stated that the petrol had been used for driving out wounded soldiers, and not for business purposes.

Coal Gas in Paris.

Although coal gas has been used in this country for some time past as a means of propulsion of motor road vehicles, it was not until recently that it was adopted in Paris for the same purpose, though previously it had been used in France for propelling motor boats and tramcars.

A New Law in New Jersey.

In a recent issue we published a photograph of a youngster eleven years old, who is a resident in New Jersey, using a Smith Motor Wheel to ride to and from school. Now we understand that the minimum age at which anyone will be allowed to ride a motor cycle in that State will be sixteen years, and no licences will be granted without examination of the candidate in the future.

Pleasant Office Situation.

Messrs. A. J. Stevens and Co., Ltd., the well-known motor cycle manufacturers, of Wolverhampton, a few months ago acquired property adjoining their works, and transferred their offices thereto. "Graisley House," Penn Road, is an old Georgian residence standing in its own grounds, and picturesque, despite its situation in a Black Country town. To conduct a motor cycle business in lofty rooms, from whose windows one looks across green lawns littered with crocuses and snowdrops, with a background of sturdy ornamental timber trees, is to make almost a joy of a modern business life; this departure is typical of this go-ahead firm

eft of Magnetos.

n March 1st the premises of Mr. D. Cox, 6, Lansdowne Hill, West Nor- od, were broken into and several mag- os stolen. A reward of £10 is offered the recovery of a single-cylinder sch car magneto, anti-clockwise, with broken off the small advance lever of contact breaker.

everal four-cylinder magnetos were stolen.

m Coast to Coast by Motor Wheel.

ecently a Mr. Hubbard, of Wheeling, stern Vancouver, rode a tricycle pro- led by a Smith motor wheel from coast coast. Lashed to the side of the rier, behind the tricycle, he carries a r of crutches. A newspaper reporter de the extraordinary statement that carried the crutches as a precaution inst accident. The real facts of the tter, however, are that Mr. Hubbard ers from rheumatism, and he uses the tches to aid him in getting about when iged to leave his machine.

e "Omniscient" Editor

ruly, the Editorial staff is accredited h a wonderful knowledge, and is ected to answer all sorts of difficult stions! The latest query which we e received in French from "*Un moto- liste livrant* 'The Blue 'Un'" when nslated reads: "Having read the icle enclosed in *l'Excelsior*, and being selves wounded and finding the deed extraordinary one, we ask if it is sible to give us further information on matter." The paragraph referred to ls with the case of Pte. J. Taylor, don Fusiliers, who has received the .M. for his extraordinary bravery persistence in avoiding being taken soner through sheltering for forty days a shell hole and then finally escaping the English trenches, which were a e distant. The story is absolutely hentic, and a medal has been awarded this brave deed, but we fear there is further information which we can give French reader.

A New Ration.

Pelican Pie: A New Ration, is the title of a new and very brightly-written Service journal, the official organ of a West Riding Division. The magazine is well written, excellently illustrated (all by members of the Division), and contains a Motoring Notes page written in humorous vein.

IMPORTANT NOTICE.

Owing to the Easter Holidays, the issue of "The Motor Cycle" for March 28th must be closed for press earlier than usual. All copy and instructions for Miscellaneous Advertisements in that issue must, therefore, be in our hands not latter than first post on Thursday, March 21st.

Motor Fuel from Coke.

L'Auto, so Reuter's Paris agency informs us, states that the French have discovered a new motor spirit which has been successfully used on a car. The fuel is claimed to be produced by the distillation of the heavy oils obtained from coke, and, so our contemporary points out, the by-products will be available for the preparation of explosives. One of the advantages claimed is that there is no deposit of carbon in the cylinders and on the piston when this fuel is used.

It is also claimed that the residues of combustion have the properties of lubricating the cylinders, and consequently less oil may be used; also that the fuel consumption is less than when petrol is employed.

The details of the fuel are somewhat meagre, but we are informed that trials were carried out with an unpurified liquid, and better results are expected when a refined form is used. The smell resembles that of wood used for wood paving.

National War Funds.

British Red Cross	9,441,433	3	9½
Tobacco Fund	149,654	0	0

The Malkin Gear.

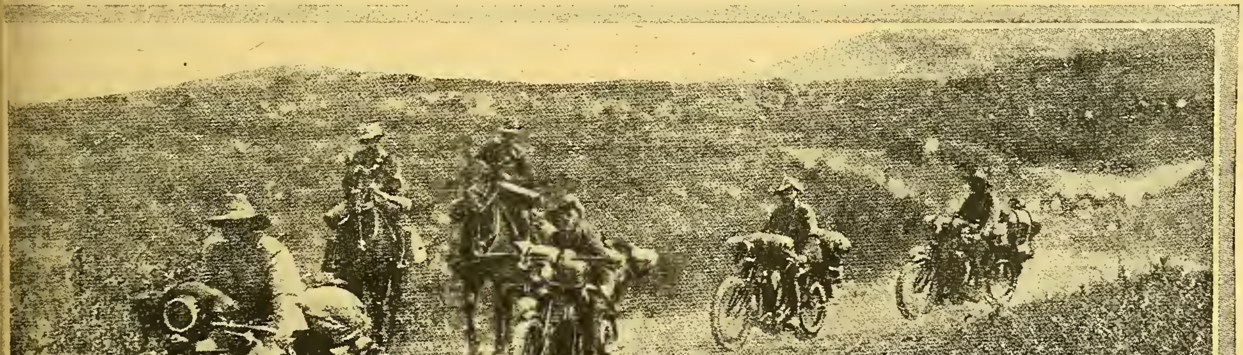
In our issue of February 21st we described a new and ingenious four-speed gear box designed by Mr. B. Malkin. Unfortunately a mistake occurred in the description. The pinion H should have been described as fixed on the layshaft and not as free to revolve on it. The gear would work quite well, however, even if the pinion H were free to revolve as originally stated.

A Petrol Rumour.

In view of a rumour that in the near future all petrol supplies for private use are to be cut off and the use of gas encouraged, we have approached both the Petrol Control Department and the Petroleum Executive, neither of which is aware of any contemplated Government action of the nature indicated. It is, of course, impossible to say definitely that no further reduction of petrol supplies to private motorists will be rendered necessary at some future date, but such a development is not now under consideration.

A North China Motor Club.

A North China Motor Club has recently been formed and the honorary secretary, Mr. J. Twyford Thomas, 2, The Bund, Tientsin, states that there is a membership of over seventy in Tientsin, while a branch is being formed at Pekin. The club is open not only to Europeans, but also to Chinese motorists, and a number of the latter have signified their intention of becoming members. The distance from Pekin to Tientsin is about eighty miles over dead flat country, and proposals are abroad with regard to making a main road between the two places, in the event of which the North China Motor Club will erect a half-way clubhouse for the use of members.



Despatch riders and the advance in the Holy Land. It is an obvious necessity that they should thoroughly understand the difficult art of securing unwieldy loads to a motor cycle. The bad roads over which they travel thoroughly test their capabilities in this direction.

THE ROYAL AIR FORCE.

DETAILS OF THE FORMATION OF THE NEW AIR FORCE.

A PAMPHLET issued by the Air Council under the Air Force (Constitution) Act shows in detail the conditions under which officers and men in the Flying Services will be transferred to the Air Force. It is curious that the initials R.A.F., representing Royal Air Force, as the new body will probably be called colloquially, are the same as those which stand for Royal Aircraft Factory and the engine which it produces. In fact, the other day we heard an R.F.C. officer, who was talking to a friend about the R.A.F., say, "I mean the Force, not the Factory." The pamphlet is headed "Transfer of the Royal Naval Air Service and Royal Flying Corps to the Royal Air Force."

Any officer, warrant officer, petty officer, N.C.O., or man who, on a date to be prescribed, belongs to or is attached to the R.N.A.S. or the R.F.C., may be transferred to the Air Force without his consent. It is also made clear that officers will have three months in which to make up their minds whether they prefer to be transferred, and that no officer will suffer either as regards pay or pension because of transfer. The following are among the principal points: Every officer or man in the Force, who is medically fit, will be liable to be called upon to go into the air, either in airships, aeroplanes, or kite balloons, and may be ordered to any station at home or abroad.

The new cap of the Royal Air Force. The two bars beside badge denote rank of wearer.

Any person transferred or attached may within three months of transfer or attachment give notice to his C.O. that he does not desire to be so transferred or attached, and the transfer or attachment is to be annulled without prejudice to the validity of anything which may have been done in the meanwhile. The duration of *attachment* shall be for the period of the war, or a period not exceeding four years, and no person *transferred* shall be liable to serve with the Air Force for any longer period than that for which he would have been liable to serve had he continued in the Force from which he was transferred. Officers and men attached will be kept for whichever period (duration of war or four years) is the longer *(sic)*.

Continuity of Service.

In the case of any person transferred to the Air Force, for the purpose of pay, pension, gratuity, retired or half-pay, and of any decoration or reward dependent on length of service, any previous service with His Majesty's naval or military forces which would have counted as service, towards pay, pension, gratuity, retired or half-pay, or such decoration or reward if he had not been so transferred, will be deemed to be service with the Air Force towards pay, pension, gratuity, retired or half-pay, or such decoration or reward.

In the case of any person *attached* to the Air Force the fact that he is so attached will not affect any righ to any pay, pension, gratuity, retired or half-pay, o such decoration or reward as aforesaid, already earne by him in such branch of His Majesty's naval o military forces to which he belonged at the date o which he was so attached, shall for the purpose o any provisions relating to pay, pensions, gratuity retired or half-pay, or such decoration or reward, b deemed to be service with that branch of Hi Majesty's naval or military forces to which he belonge at the date on which he was so attached.

Questions of Rank and Pay.

It may be taken as a governing principle that n officer or man will suffer during the war by reason c transfer to the Air Force in respect of pay of th rank held by him in the Nav or Army immediately befor transfer; an officer or man however, may be required t relinquish his temporary c acting rank under the existin rules of the Services. Nor wi officers or men suffer through an revision of the rates after the wa as regards pay or pension of th rank held by them on the date c such revision. At the same tim it must be borne in mind that cer tain emoluments have only bee authorised for the period of th war, and this limitation mus equally apply in the Air Force.

Full particulars as regards pa of officers and other ranks are given in the pamphlet the corresponding ranks and appointments in th existing Flying Services, and information as regard allowances, pensions, half-pay, income tax, priz money, prize bounty, and war gratuity.

In the Air Force motor cyclists are counted as i the non-technical branch, though drivers of steam an petrol waggons are accounted technical.

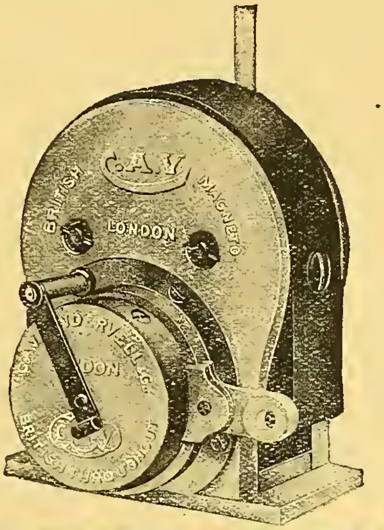
Wing commanders and wing observers R.N.A.S. and wing commanders R.F.C., or officers of equiva lent ranks in the technical and administrative branche become lieutenant-colonels in the Air Force. In th same manner squadron commanders and squadro observers R.N.A.S., and squadron commander R.F.C., become majors. Flight commande R.N.A.S. and flight observers R.N.A.S., and fligh commanders R.F.C., become captains, flight lieu tenants and observer lieutenants R.N.A.S., and flyin officers and observers R.F.C. become lieutenants, an probationary officers become probationers.

GOODS MADE IN GERMANY.

The proprietors of this journal, being fully in accord with the recommendations agreed upon at the Paris Economic Conference, give notice that they will not permit the advertisements of new goods manufactured in enemy countries to appear in this publication, either during or after the war.

ILIFFE & SONS LTD.

To Motor Cyclists!



WHEN the question of a MAGNETO crops up, take the tip from the man at the front, and plump solidly for C.A.V. — the All-British Magneto that is daily proving its worth under the most strenuous of War conditions.

FROM THE MESOPOTAMIAN EXPEDITIONARY FORCE.

A BELATED season's greeting card has just arrived from Maj. J. W. Coring, A.S.C., who is in Mesopo- . The humorous rhyme, which pre- a list of battles, runs :

> T medal of ours with its ribbon and bar
> T of the crushing defeats of the Crescent and Star.
> 'T a pleasant reminder to friends far away
> T more than one Turkey is ruing '*The Day.*' "

e list of engagements is longer than would have imagined, twenty-six the number given, from Fao to the gement at Ramadie.

* * *

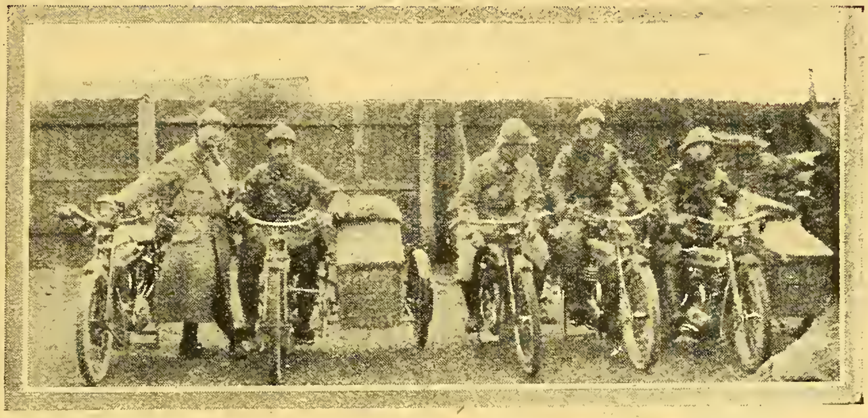
FLAT TWIN ENTHUSIAST.

A D.R. of a Divisional Signal Company in Mesopotamia writing under the *nom de plume* "Tiffy" sends a iptive letter on the way flat twins tanding up to their work.

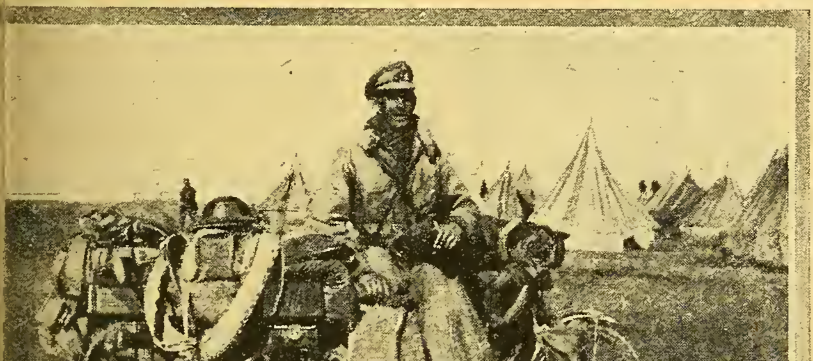
"n our Division we have both Triumph Douglas machines, and both makes of ines are standing up to the terribly work wonderfully well. The las has made quite a name for itself here; even riders who did not care he Douglas have had to say it is rkable the way it behaves. The nph bas not enough clearance, and ront springing is not all that can be ed. The clearance requires to be at 6in. in consequence of the sand and which is 6in. to 12in. deep, and in places - even more. Although in some places it is quite decent travelling, in others it is like riding over ploughed fields—in fact, in certain districts the land has actually been ploughed up and left. When travelling one has to be always on the look out for holes and dips which one comes upon suddenly, and in these instances the Douglas's high clearance is a benefit. The Triumph's kick-starter and hand-controlled clutch, however, are a blessing.

"If tyre manufacturers had to test their tyres on the wet, muddy roads which prevail out here to judge their non-skidding qualities they would give up in despair of ever making a non-skid cover. It is worse than Thames or Derbyshire mud. On these roads the Douglas is supreme.

"*The Motor Cycle* is always welcomed, and much looked for, as it keeps us in touch with things at home. For my own part, I think the horizontal twin has come to stay, and I want nothing better than to get back on Blighty roads with one."



French despatch riders at the rear of the fighting line. Many thousands of the wicker sidecars shown are in use on the French fighting front.



pl.-Art. H. Russell, who is despatch riding in Macedonia. The ample kit is worthy of note, and the fact that the carriers stand such loads speaks well for their construction.

D.R.'S OF THE FIRST EXPEDITIONARY FORCE.

FROM a recent number of the *Gazette*: "Corps of R.E.'s.—Temp. Lt. to Temp. Capt., to retain their acting rank where specified, H. H. Berlandina and R. G. Larkin." Both were competition riders before the war, and were among the D.R.'s who crossed over with the first Expeditionary Force.

WAR OFFICE PURCHASES.

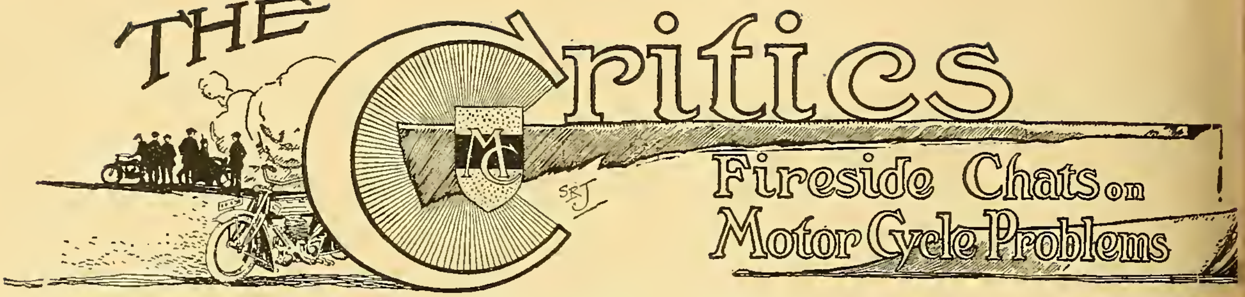
THE statement of War Office purchases, as quoted by Mr. Macpherson, is as follows :

TOTAL.—£270,000,000 of manufactured goods. FOOD.—Preserved meat, £12,000,000; tea, 84,000,000 lb.; sugar, 177,000,000 lb.; milk, 145,000,000 tins. TOBACCO.—Pipe and chewing tobacco, 8,500,000 lb.; cigarettes, 11,000,000 lb.

* * *

MOTOR CYCLIST WINS THE D.C.M.

WE congratulate an old reader of *The Motor Cycle*, Gnr. A. E. Milsom, M.G.C., on having been awarded the Distinguished Conduct Medal. Gnr. Milsom resided in Geneva. On a recent occasion he followed the armoured cars into action on his motor cycle, though under heavy fire at 800 yards from the enemy trenches, in order to maintain communication between the cars and headquarters. This enabled early information of the enemy's disposition to be sent back to H.Q. The deed is one of which any man might be proud, and the decoration was certainly well earned.



THREE-WHEEL DESIGN.

"BEASTLY things!" said the Novice, with a vindictiveness quite foreign to his usual mildness of speech. "If I could afford anything better, I would not be found dead in one."

The Novice had been out all day through mud and slush on his sidecar; hence this unusual outburst. "And yet," he pursued, "one hears of manufacturers still preparing special luxurious sidecar models for after the war. I call it absolute folly."

"Why?" The question was shot from the D.R. The Novice gave him a cautious look. He did not like arguing with the discharged soldier, owing to the latter's propensities for becoming personal.

"Well," he pursued, a shade nervously, "who is going to buy a beastly exposed, uncomfortable, and unsociable thing like a sidecar if there is anything better to be had?"

"Oh, bilge!" expostulated the D.R. "People have been talking like that ever since sidecars came in, yet for years they have held their own. Has not the sidecar had a hundred rivals and outlived them all? What about the scores of cycle cars? The Morgan is almost the only one that survives, and there are numbers of men who would prefer a good sidecar outfit even to a Morgan."

"That's true," put in the Manufacturer. "But why was it the cycle car did not survive? Simply because every tinker and cobbler in the back streets of Birmingham tried to scrape something together and sell it to an enthusiastic public under the name of a cycle car. The result was that the type earned an abominable name, and decent firms steered clear of it."

With this the Journalist agreed. He said that the failure of the cycle car was not owing to its impracticability, but for want of support from real engineering establishments, and from general prejudice caused by built-up abortions. "Some of the little Humberettes, for instance, were marvellous," he added. "And now that such engineers as Alfred Scott——"

An Unworthy Prejudice.

But at this the D.R. held his head and groaned loudly. "I can stand Humberettes and Morgans," he said, "but when you begin to throw Scott Sociables at me I give in. Of all the outlandish ——" but words failed him. The Journalist was regarding him narrowly.

"I should have thought you were too much of an engineer to give way to such petty narrowness," he said. "You, like scores of others, do not like the Scott Sociable simply because it is unconventional—because you are not yet used to it. You would discourage originality in design—the very thing on which progress is dependent—simply because it is 'ugly.' Was not the sidecar 'ugly' when first it came in? Did not the first disc wheels you saw strike you as being hideous? Even the railway engine, the motor 'bus, the motor car itself, have all been hideous in their time, and such bigoted and narrow-minded critics as you have condemned them on those childish grounds. Where should we be to-day if the world's engineers had been discouraged by criticisms levelled at the appearance of their inventions, and what, after all, is the Scott Sociable?"

The D.R. said that he knew, but would rather not say.

Price and Comfort.

"I'll tell you what it is," pursued the J. "It is purely and simply your beloved sidecar outfit, possessing all its advantages, but aiming at eliminating its numerous weaknesses. The so-called luxurious sidecar outfit is the freak—not the Scott Sociable. In the sidecar you have your motor cycle, which is practically unrideable till you attach a sidecar—a separate and distinct unit—to it. You do so by means of couplings and bent stays, which are apt to bend or creep till the whole thing is out of alignment, then you proceed to ride, experiencing all the discomforts of the solo mount, enjoying none of the comforts of the rigid vehicle."

"Oh, go on!" interposed the D.R. "The sidecar has proved itself pretty well, anyway."

"That's just my point," pursued the J. "It has proved itself so well that it is worth constructing on engineering lines, designed as a three-wheeler throughout, and affording the advantages that a rigid double-track vehicle should afford. I consider that the general lay-out of the Scott Sociable is an excellent example of a truly engineering attempt to bridge the gap between the sidecar and the light car."

"Oh!" exclaimed the D.R.; "so you do think that the sidecar will live on, after all?"

"Certainly I do—but only as an attachment. I think that the hundred-guinea vehicle on the lines of the Scott and the Morgan will absolutely oust the heavy type of outfit vulgarly known as a combination. No one will think of spending £110 on such an outfit when at the same price or £10 more he can purchase a vehicle affording car comforts."

There was a moment's silence. "
I cannot understand," said the
eventually, "is that everyone does
buy a Morgan instead of frivolling a
his cash in a sidecar outfit. Why did
Novice, for instance, go and buy a bea
sidecar when for approximately the
money he could have bought a Morga

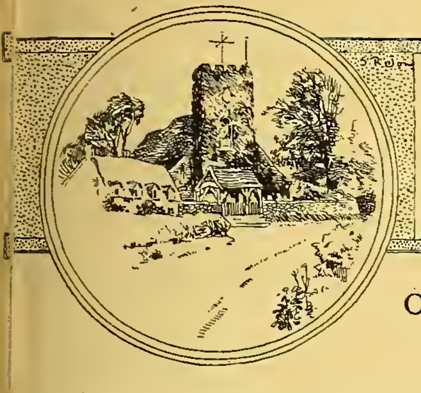
"I really do not know," retorted
Novice. "I agree with you that it
an act of extraordinary folly. Poss
it was because the workmanship of
£100 motor cycle was infinitely supe
to anything in the way of cycle
then obtainable. It was peculiar to
breed, almost without exception,
they employed gas piping for the cont
while the finish simply made one gid
Anyway, the Journalist is fearfully
on the Scott Sociable, and I must a
with D.R. in that the inventor has
out of his way to be unusual."

The Journalist did not think so.
thought the design of the Scott Soci
quite obvious and straightforward.
a three-wheeler it possesses those ad
tages which the sidecar has proved to
very real advantages. It has only
tracks instead of three. It can turn
the length of its own wheelbase. Exp
ence on the track has shown that
common tricycle principle, one w
centrally in front, is unsafe and
possible at high speeds. The single w
behind is all right, except that it has
withstand enormous side stresses, in a
tion to driving. Therefore we are redu
to the one and only practical design
three-wheeler—the right-angled tric
Why should a right-angled tricycle
freakish, and any other form of tric
permissible? Personally, I am by
means convinced that the right-angle
not the best of them all."

Four Wheels?

"It may be," said the Manufactu
"but why tie oneself down to th
wheels? Why not avoid all taint
freakishness and go in for four in a se
ible, straightforward manner? You yo
self state that the cycle car is a pract
proposition, and the general public wo
infinitely prefer it to any type of th
wheeler."

The Journalist thought a mome
"We are treading on rather diffi
ground," he concluded. "What we
discussing is the vehicle to fill the
between the motor cycle—with light s
car attachment if you like—and the li
car. As soon as you get into
wheels you arrive at a different c
which, to be truly roadworthy in ev
sense, must be much more costly t
the three-wheeler.



THE D.R. THROUGH FRENCH SPECTACLES.

ON THE EXPLOITS AND ADVENTURES OF BRITISH DESPATCH RIDERS.

IN the issue of our French contemporary, *L'Auto*, of February 9th, there appeared a paragraph stating that in view of the cordial relations which he always existed between British and American sortsmen and French sportsmen, and especially since t whole of civilisation has gathered togher under one flag—the free children of t United States, of England, and of Gaul—they are now united by fraternal affection, ad this has instigated our contemporary to anounce its intention of printing in English a certain portion in its paper concerning vious sports. Most happily *L'Auto* deals i sport of all kinds, but there are occasnally to be found in its pages references to motor clists. The paper has recently published an interesti article entitled "*Les D.R.*," which gives us an iight into the life of our despatch riders as viewed b a Frenchman, and on account of its interest we rproduce it in English.

The Cavalier de Dépêches.

"When on leave in Paris you have doubtless riced English soldiers wearing a blue and white anlet on each arm. This is the brassard of the signal corps, which includes those who keep up communications, or transmit messages, consisting of ordinary signallers, telegraphists, telephonists, pigeon post, etc., and, finally, motor cyclists, who often wear a winged wheel embroidered on their tunics, with the itials 'D.R.' D.R. means despatch rider, erally *cavalier de dépêches*—originally a scout in e Colonial wars mounted on a swift English steed. ut in this terrible war it means an acrobat wearing oggles, leather gloves, and mounted this time on two nd three-quarter horses, or even on four solid horses.

"D.R." means cavalier de dépêches—riginally a scout in Colonial wars, ounted on a swift English steed.

One cannot imagine the work involved for the vibrating steed and for the man who controls it over the ordinary (!) surfaces of the road at the Front, nor can one imagine it at the rear, where there are real roads. Only our readers who have been to the Front can form an idea of the true conditions. In liquid mud, they drive, leap, and bound, especially in winter, on roads in the fighting portions of the line made of wood logs, over terrible bumps, on paths made of brick, which are fatal to the tyres, and over a terrible road of planks, but even these, after the *pavé* from Ypres to Cassel, seem like tracks superior to that at the *Parc des Princes!*

A Wonderful Ride.

"Consideration must also be taken of the climate in which the English D.R.'s are riding in Belgium all the winter—in water, under water, without a day of sunshine, and never on a dry road. How hard the enemy has made their life! The mud is worse than anything else. For a car or a lorry it is nothing, but on a motor cycle! Mud which renders the surface treacherous and provokes sideslip when riding in front of heavy vehicles, and rendering the smallest punctures dangerous. Engine troubles in this hostile ocean are perhaps more unnerving than elsewhere. I knew one D.R. on the Somme who one night of inky darkness—lights were forbidden—covered sixteen kilometres of shell-torn roads without a clutch, the exhaust lifter having broken, but he reached his destination in spite of the fact that his chain was constantly jumping off. On he rode without delaying, among convoys of artillery, and literally between the legs of horses. Can one imagine the will power he had to have? After that he went to sleep on a plank, for the English hate straw. They go to bed on cement, wood, or more frequently on the bare ground. Nothing stops a D.R. The message service continues like a railway time-table, with just the same regularity and controlled to the minute, by night and by day,

"Ceci." vaincra "Cela."

The D.R. Through French Spectacles.—

from G.H.Q. to the infantry in the lines and in direct communication between all units. It is a model of organisation. The D.R., who carries neither steel helmet nor revolver, except when actually going to the Front, according to the English custom, goes on his motor bicycle wherever it is humanly possible. I have seen riders driving in a mist, a few hundred metres from the enemy, in places in which, if the view had been cleared, nothing could have lived for a second. For the British possess the admirable imprudence to go and discover. They hate communication trenches, and shells are not the worst enemies of the D.R. It happens sometimes that the D.R., hearing nothing but the noise of his engine, does not notice shells passing before him, and often enters the 'cone' of an explosion. Shrapnel is also disagreeable, but the free exhaust covers all other sounds, and he can only hear the heavy explosions above his head, and he sees with some annoyance a cloud of black smoke, and if the infantry appreciates the flight of the hornets, the D.R. is content to extend his back, with a tardy regret, of course, that he has left his tin hat at Signal Headquarters.

Sang Froid.

"One day in an advanced post on the Somme, D.R. was on his knees repairing his belt, and Germa shells were methodically coming over. 'The ne lot will be for us,' was the public opinion, and t public was a dozen signallers, who quietly descend into their dug-out, and the following shells continu to arrive, fired at one hundred an hour, or perha more.

"It was only the wall at the foot of which h flung himself which saved the D.R. Two tons earth, pebbles, and various rubbish fell from t heavens on the motor cyclist. When the shower ha subsided he shook himself. An officer approache 'Well, X,' said he, 'how did you like that?' T D.R. smiled, and said simply, 'Oh! Killing!' *Ce veut dire: Tuant. Comme nous dirions. À mour de rire; mais, justement. À mourir.* At which ever body burst out laughing. **Car les Anglais*—kee smiling—*devant les 150, comme les Français, 'ga dent le sourire!'* Is there a German word for that

"HERVÉ LAUWICK."

---

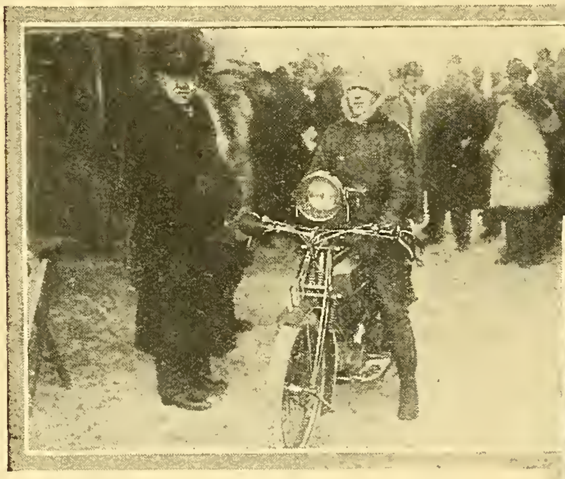
* The author endeavours to explain that the English, like the Frenc "keep smiling," despite the arrival of 150 mm. shells.—ED.

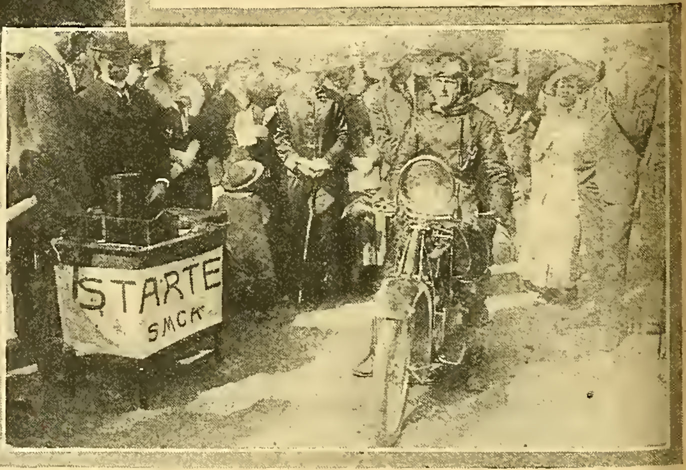
COMPETITIONS IN SWEDEN.

A Three Days 1,000 Miles Trial.

TWO photographs have been sent to us by our Swedish correspondent, Mr. Gustav Göthe. One of the illustrations shows Mr. Göthe on a 3 h.p. Enfield—a make which he has ridden a good deal in competitions since the occasion of the May Trophy in 1912. The May Trophy is the severest Swedish motor cycle trial, over a course of 1,000 miles in extent, which has to be covered in three days. The route is Stockholm, Malmö, Gothenburg, and Stockholm. Note the huge head lamp with which the machine is fitted, which is necessary when riding through the Swedish woods at night time. The ol gentleman standing on the left of the starter is Genera Sir Victor Balck, who was knighted by King George and is a world-renowned patron of sport. On thi occasion Mr. Göthe gained the highest award.

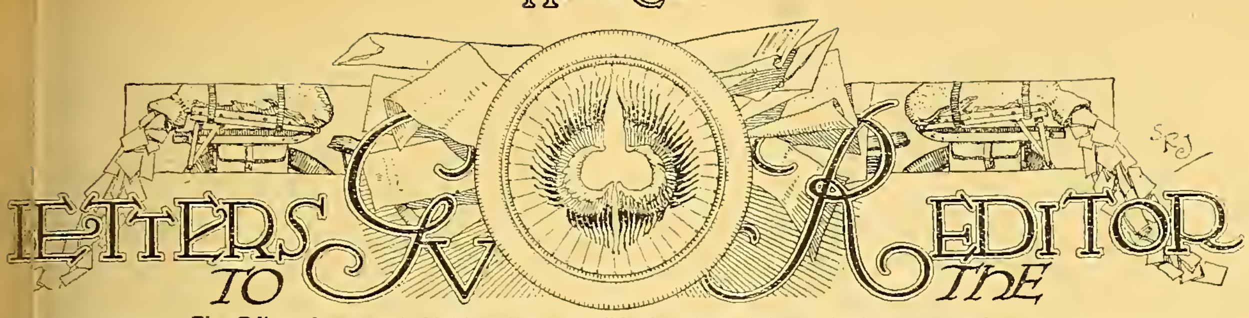
The other picture is of an incident in the Mid winter Trophy, 1917, which was the last motor cycl competition held in Sweden. It was held on th occasion of the Northern Games, and the snow wa tremendously thick. The course was not a very lon one, being only 200 miles, but owing to frost an snow the going was difficult. On one occasio the competitors had to descend to the beac and cross an arm of the sea which was froze over. Again Mr. Göthe won a highest award. The machine he rode was a Husqvarna— Swedish-built motor cycle fitted with a Moto-Rêve engine, and designed by himself.





(Top) Mr. Gustav Göthe aboard a Swedish-built motor cycle—the Husqvarna.

(Bottom) The same rider and his Enfield, which he used in the 1,000 miles Swedish trial.



LETTERS TO THE EDITOR

The Editor does not hold himself responsible for the opinions of his correspondents.

All letters should be addressed to the Editor, "The Motor Cycle," Hertford Street, Coventry, and must be accompanied by the writer's name and address.

BRITISH MAGNETOS.

ir,—In reference to Mr. Pendrell's interesting paper on "Motor Cycles," and relating particularly to his remarks concerning British magneto mouldings, your readers may be interested to know that one British magneto firm alone (the one with which I am connected) has supplied over a quarter of a million eminently satisfactory British mouldings fitted to its magnetos used exclusively for aeroplanes.

H. WARREN.

HOW MANY GEARS?

r,—In *The Motor Cycle* of February 21st I noticed a photograph of a machine fitted with a three-speed Armstrong hub as a countershaft gear.

our correspondent, Mr. J. W. Taylor, will no doubt be interested to know that the machine is at present in my possession, and I can bear out his statement that the gear was a valuable addition to the machine.

F. DEWHURST.

AN ATTRACTIVE RUNABOUT.

r,—With reference to the photograph you published in *The Motor Cycle* dated March 7th of Japanese motor wheel enthusiasts at Nagoya, the machine on the extreme left appears to be a "pocket edition" of the Morgan Runabout, but I have not seen anything in this country on similar lines, except invalid carriages.

should be much obliged if any reader could give me particulars as to whether the idea is practicable in England: and if a three-wheeled machine of this type would be rated as a motor cycle.

ARTHUR R. PERRYMAN.

FOOTREST POSITION.

r,—For solo riding amidst traffic, tramlines, and grease is it not far preferable to have footrests almost directly beneath the rider instead of footboards, which are invariably placed much further forward?

know of no machine which gives so comfortable and secure a position as that obtainable on a Rudge with both pedals down.

oubtless the W.D. machines are sound in this respect, and I hope "Motor Manufacturers" will bear the point in mind after the war.

he sit-up-and-beg position is no use on bumpy greasy roads; but on the other hand the average business man will not care to ride spread-eagled. I plump for footrests, placed well back, and semi-T.T. handle-bars. What do Black Country riders say?

ALLON.

GUDGEON PIN SCREWS.

Sir,—I have just met with a little incident which might interest your readers, and make them more careful, when taking down their motor cycle engines for cleaning purposes, e., to inspect the gudgeon pins. I was coming back from Manchester, and when five miles from home the machine, which had run beautifully all the way, pulled up suddenly, gave a violent lurch forward, nearly throwing me and my passenger in the air, and then stopped dead, and would not move an inch. We then had to push the machine home.

I took the engine down, and found that the grub screw, which holds the gudgeon pin from coming out, had worked loose, and finally found itself playing about the bearings, until the fatal moment came, when it jammed itself between the connecting rod and the flywheel. It was so fast that I had to cut it out with a hammer and chisel. Luckily, no harm was done, but it has been a lesson to me.

G. H. MARSHALL.

VALVE TIMING.

Sir,—The following method of timing a lightweight four-stroke may interest your readers. The advantages are no blow back through carburetter and exhaust noise greatly reduced.

Timing.—Exhaust opens at twenty-nine minutes past and closes at five past. Inlet opens at seven minutes past and closes at twenty-two minutes to. This is an attempt to follow what has been described lately as aeroplane practice, *i.e.*, late opening of inlet valve, and is successful as above with no disadvantages that I can see.

R. L. BOYD.

ARMY MOTOR CYCLES AFTER THE WAR.

Sir,—As unfortunately I have not had the pleasure of reading your estimable journal for a considerable number of moons, I do not know if any suggestions have already been made regarding the after-war disposal of the many bicycles which have done admirable work and which will no longer be required for military purposes.

However, may I make the suggestion that these only be sold to members of H.M. Forces (wearers of the wound stripe to have first choice)? I should be glad to know the views of others on this matter.

Douglas, Triumph, and P. and M. machines are doing marvellous work on shocking roads here.

Macedonia. J. H. MORTON.

A TRIBUTE.

Sir,—Having seen so many letters in your valuable paper relating the merits of various machines, I would like, with your permission, to add my humble one.

I have had various makes of machines, but since the war mostly Triumphs, which I must say "never let me down."

I am in charge of a Motor Despatch Riders' Section attached to a war station, thirty miles from a railroad, and situated in a mountainous district. Our "trusty 'buses" (Triumphs) average seventy miles per day over those mountain tracks, and after a mileage of 11,000 they have recently been passed "in perfect condition."

I must say there is room for improvement in the mudguarding, which I consider is not adequate, and I hope the makers are considering this for their future models; otherwise, the little Triumph is perfect in every detail, as the manner in which it stands the great test to which it is being subjected in this war sufficiently shows.

GEO. I. P. GROGAN (Sgt.), Despatch Rider, R.E.

STEAM MOTOR CYCLES.

Sir,—As a reader of your valuable journal for many years past, I have recollections that a few descriptions and illustrations of attempts to produce a steam-driven motor cycle have appeared therein. Now that it is so difficult to obtain petrol, does the steam-driven motor cycle offer any solution of the problem, in the use of a lower grade oil, or acetylene, for the purpose of raising steam?

It is at once evident that there are many difficulties to be overcome, but are these difficulties, in the opinion of expert engineers, insurmountable? If it is not possible to construct a solo machine, will the sidecar machine meet the case, by arranging its chassis to contain the boiler?

The many advantages, other than that of fuel, are, I think, well worth consideration. It would be very interesting just now to hear from an engineer who has studied the matter whether or not it is likely that such a machine could be produced—one that would have a good chance of being successful commercially.

STEAM.

A LAMINATED SPRING SYSTEM FOR THE REAR WHEEL.

Sir,—In your issue dated February 7th you illustrate a spring frame designed and patented by Pte. Markham. If this gentleman, and other interested parties, will turn up your issue of May 17th, 1917, they will see therein described an account of an actual road test carried out by *The Motor Cycle* staff with a spring frame Brough. This spring frame was designed in 1915.

GEORGE BROUGH, A.M.I.A.E.

LIQUID AIR AS A MOTOR FUEL.

Sir,—We have noticed from time to time references in your paper to the possibilities of using liquid air for the propulsion of motor vehicles.

Without wishing to discourage any further attempts in this direction, we would like to say that, although it is possible to drive an engine by means of liquid air, and that it has, in fact, already been done, anyone with a knowledge of the physical properties of liquid air can by a very simple calculation readily convince himself that it is not an economical proposition.

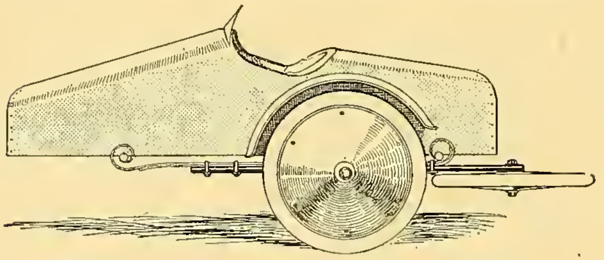
Should, however, any of your readers feel inclined to investigate the subject, it may interest them to know that liquid air is obtainable at our works at 10s. per gallon.

THE LIQUID AIR AND RESCUE SYNDICATE, LTD.

A CHEAP SIDECAR.

Sir,—I am forwarding a rough sketch of a sidecar body that I built for a friend of mine just previously to going as a D.R. to the Front, whence I am now home on fourteen days' leave.

I might mention that the body was built, painted, and upholstered within six days, and that my friend has used it in all weathers. He has now fixed it up for "gas bag stunts"!



A home-built sidecar produced at a cost of 19s. 5d.

The chief items of interest are strength, lightness, and comfort. It is also very roomy, and is fitted with a celluloid windscreen; thus the passenger is right down out of all wind. The cost amounted to 19s. 5d. The following are some of the chief particulars: Length, 6ft. 3in.; height, front 14in., back 10in.; inside, front at cockpit 20in.; inside, back at cockpit 17in.; leg space from seat back, 4ft. It was painted black, upholstered in green, and made of two sheets of three-ply, with ash and deal framework.

GEO. F. C. SAUNDERS.

GOODS MADE IN GERMANY!

Sir,—I do not know if I am quite qualified to ask for space to air my views on the above subject, as I am not a motorist, my connection with your paper consisting of sending it weekly to a B.E.F. D.R.

Long ago my wife and I agreed to have no further dealings with Germany, but we shall need the encouragement and assistance of British manufacturers to carry it out, whilst also being prepared ourselves to make some sacrifice.

My object in writing, however, is to call attention to the subject of hotels, which depend so much upon the patronage of automobilists. Many of these hotels, as everybody knows, were owned, managed, and staffed, before the war, by gentry bearing such names as Kopp, Kaiser, Bauermaister, etc., etc., and unless something is done to prevent it some of your correspondents who have written expressing approval of your action will some day find themselves actually putting up once more in uncongenial company.

I suggest, therefore, that a register be kept of all hotels from which the German element is eliminated, and a black list of those "under suspicion."

The Automobile Association and Chauffeurs' Society, wor
ing upon the same lines, could practically exterminate u
desirable alien drivers, both public and private, and the
is plenty of scope in many other directions for energet
people who mean business.

M. J. HAWKINS.

Sir,—I am writing to ask you not to waste any more
your valuable space by continuing the correspondence
goods made in Germany. No sane-thinking person could
of any other opinion than that of the publishers of *T.*
Motor Cycle, and I consider it a waste of time to argue t
matter further. Whatever a few readers may think, I a
sure the publishers will not deviate from the course whi
they have decided to take.

I think I may claim to have a slight knowledge of t
German as he is, and not as some people appear to thi
him, as I was interned in a German camp for a considera
time.

People like Tom E. Tanner talk of shaking hands wi
the Hun after the war, and treating him like a brothe
One agrees nothing is finer than the spirit in which t
sportsmen will shake hands after a fight, but to shake han
with the Hun would be like shaking hands with, say, a c
whom one had knocked down for bullying.

A. ARNOLD.

Sir,—I would like to say a word about your admira
notice *re* Hun trade. If everyone in this country adopt
a similar attitude toward the unmentionable Hun, we wou
be assured of a cleaner air in our trade circles after t
war. Who will be able to shake hands with a Hun aft
the war without staining himself with the taint of filt
barbarity, which must cling for ever to these disgusti
outlaws of every decent feeling, every code of honour, a
even the sportsmanlike instinct of a common mongrel do

Snivelling remarks are heard on many occasions fr
weaklings who have not the grit or common courage
our gallant men in the field, or that grim purpose whi
made the Englishman the most successful man in all t
past great struggles.

America recognises the truth of this in her public li
and she has no use for half-hearted citizens who reta
everything by their weak interference. An army officer w
dared to show sympathy for the Hun in America was giv
twenty-five years' imprisonment last week. That is the w
to treat such traitors. Will our people ever be efficie
in the running of such vital matters? I think not—un
they are badly bitten by the parasites who write sympath
ing with the unutterable Hun.

Let us win the war, and then talk over things with the
poor degenerates; for we English are over-charitable a
just, and I am sure we shall never summon up enou
decision to "out" the traitors who seem to have such
hold on our national interests.

JOHN G. GRENFELL.

[Now that readers of various shades of opinion have had
say on this matter, this correspondence must be close
We may say that the great majority of our corresponden
have been wholeheartedly in favour of our policy, whi
has been followed by many other journals.—ED.]

CARBURETTER ADJUSTMENT.

Sir,—I read with particular interest some notes whi
appeared a few weeks ago in your esteemed journal o
the *nom-de-plume* "Triumph," which dealt with t
experiences that particular correspondent has had with t
Binks carburetter.

My interest lies in the fact that I, too, have failed
solve the question of satisfactorily running on the *main* j
of this carburetter. I may say that I have not fou
the slightest difficulty in obtaining flexibility, slow runni
or acceleration—up to a point, of course, as far as pow
output is concerned—from the first and second jets; b
attempt to do more than "smell" the main jet, and t
game is up immediately.

I have persistently for over a year worked to overco
this difficulty by all manner of juggling with the sizes
jets in a single-cylinder 86×86, and also a 90° twin of t
same dimensions of cylinders, but I am just as near succe
to-day as when I started. Strange to state, the nearest
satisfactory results from the main jet that I have got h
been with 0, 3, 5, but this only extends to even runni
and, of course, with such a small main jet the pow
would be better described as "donkey" instead of "horse
It will be needless for anyone to inform me that I ha

failed to do so and so with the bottom air holes. I am quite conversant with the fine points of the instrument, also I know all about air leak, etc., and it is just for these reasons that I am disappointed.

The twin engine appears to take more kindly to the Binks than the single, and I myself take kindly to the carburetter on account of the undoubted controllability of the machine it offers when in traffic and on the smaller jets, but I should like very much to read some other user's experience.

I am not, it will be noted, making any complaint regarding the half wineglassful of petrol which is invariably wasted when changing jets.

The maker issues instructions, which I have studied carefully, of how to overcome any and every difficulty, but somehow they all appear to fail when tried with the main jet.

H. A. CONNELL.

PETROL FOR SOLDIERS.

Sir,— I am writing you with reference to the granting of petrol permits to men on leave from the B.E.F., etc.

I came on leave about three weeks ago, and lost a whole day in London in order that I might call on the Petrol Control Board. After filling up "umpteen" forms I was granted the paltry allowance of two gallons for motor cycle and sidecar. Surely something can be done to raise this allowance.

C. A. S. THORNTON.

Sir,—I am at present in a convalescent hospital, and thought it might interest some of your military readers to know that a permit to obtain and use petrol can be obtained from the Petrol Control Committee, if unable to reach home from the hospital by any other method.

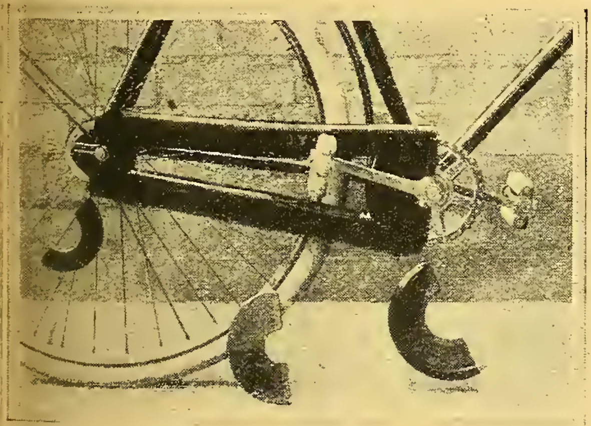
I applied for a permit, and was much gratified at the very prompt way my application was dealt with. I have been allowed two gallons per month for two months, and this will enable me to reach home every Sunday.

It was through your answer to my letter *re* granting permits to men, as well as officers, on leave or convalescent that I put my case forward, and I wish therefore to offer my thanks to the "Blue 'Un," which I shall continue to take as usual whatever the price, and I am quite sure your military readers will all support your much discussed "Goods made in Germany" notice against the attacks of Mr. Chas. S. Ives and his "Conchy" supporters.

SGT. H. OWITZER, D.R., R.G.A.

CHAIN CASES.

Sir,—With reference to the Limana chain case, described on page 177 of *The Motor Cycle* for February 21st, you may be interested to learn that nearly twenty years ago I embodied this idea in a pedal cycle frame, which was built by Messrs. Humber, Ltd., at their Lower Ford Street works, Coventry.



Showing a tubular construction which formed the chain struts and gear case of a machine made many years ago.

If my memory serves me rightly, the machine was finished during the twelve months following the disastrous fire at these works, and while Mr. Alexander Craig, who was my successor, was works manager.

T. W. BLUMFIELD.

LUBRICATION IN INTERNAL COMBUSTION ENGINES.

Sir,—Under the above heading in your issue of February 7th you publish a letter from F. Strickland, which contains statements that are obviously absurd.

One of these is to the effect that he knows of an internal combustion engine "which was running perfectly after seventeen years' continuous work, during which time the main bearings were never adjusted and the bottom ends only once," and continues to the effect that "owners often scrap these engines in perfectly good condition (?) to make way for a more modern type."

Any engine that had done so much continuous work on such little attention would have been fit for the scrapheap many years ago.

After long experience of both land and marine types of steam and internal combustion engines by the best builders, I must say that no engine ever constructed could possibly do anything approaching such a performance.

His remarks as to the constant reborings of steam engine cylinders are also exaggerations. I have sailed in a vessel the engines of which were thirty-two years old, the cylinders of which were never rebored in that time, and were never lubricated, and yet were perfectly circular, and the working faces of both valves and cylinders were glass hard—too hard, in fact, to be marked by a file. Perfect surfaces such as these are common in all large steam engines after a few years' careful running.

Internal combustion engines as fitted to motor cycles, etc., with their haphazard oiling systems and exposed working positions, could certainly never hope to equal the life of large slow-speed engines with positive lubrication (such as are in use for electric generating plants, etc.), and working in specially constructed buildings, with constant attention. Still, they never run the period your correspondent claims without many overhauls.

RAYMOND W. SHIMMINS.

RECORD SPEEDS.

Sir,—I was pleased to read in the paper I am now taking for the time being, the *Daily Mail*, the following table:

Light and electric telegraph	186,000	m.p.s.
Shell near muzzle 6in. gun	2,500	ft.p.s.
Shell from 75 mm. gun	1,600	,,
Sound	1,100	,,
Revolver bullet near muzzle	500-800	,,
Tip of blade of airscrew	400	m.p.h.
Fast aeroplane	150	,,
Fast aeroplane with high wind ...	200	,,
Fast motor car	120	,,
Express train	80	,,
Fast steamship	40	,,
Bicycle (pedalled)	32	,,
Racehorse	30	,,
Man skating (for a mile)	24	,,
Man running (100 yards)	20	,,
Man running a mile	13	,,
Man walking	4	,,

I realise, of course, that one cannot get to New York on a motor cycle, nor for that matter by an express train or a fast motor car. At the same time I am surprised to note no mention is made of our dear pal the motor cycle, and to any keen and enthusiastic motor cyclist it is something one cannot understand. Comparisons on speed are made in regard to the fast motor car, the express train, etc., but the fast motor cycle is not given a show. It is all the more surprising when one reads that the lecture was given by so eminent a person as Col. Mervyn O'Gorman, and when one realises to-day how many flying men were previously keen and enthusiastic motor cyclists. Why the motor bicycle has been omitted in making these comparisons is something we should all like to know. At the same time I may be excused when I say I think it would be very hard indeed to find a pedal cyclist who could do 32 m.p.h., though it may have been done. I was wondering whether between the fast motor cycle and the pedal cyclist there should not be the fast motor cycle which has beaten an express train, and should therefore take its place correctly between the fast motor car and the express train. I trust you will pardon my writing you lengthily on this subject, but I feel that my dear old friends should have a place in this comparison of speeds.

P. J. MACREADY.

[A motor cycle has exceeded 100 m.p.h.—ED.]

LITTLE SKETCHES IN PRE-WAR FRANCE.

III.—ROUEN AND HOME AGAIN.

AFTER a week of kaleidoscopic sight-seeing (the long galleries of the Louvre, the mechanical naughtiness of the Bal Taberin, the chill dignity of Napoleon's tomb in the Invalides, the Luxembourg statue wreathed with *immortelles* in remembrance of the lost provinces, Puvis de Chavannes paintings, and delectable meals in odd forgotten corners of Paris) our little Douglases were dragged from their obscurity in the rear of the wine shop, and on a fine Sunday morning we set out for St. Germain to view Paris from the famous terraces. A rough road and an uneventful trip, save for the protests of a *gendarme*, who objected to our deserting the atrocious *pavé* for the path, in the face of the fact that there was no "*Piste cyclable*" notice up. We placated him, and continued as before, little boys scurrying in front of us crying, "*Gare au velo!*" at the top of their voices. St. Germain is a quaint little mediæval town. While my friend was photographing a church interior I was accosted by a "*chemineu*" (beggar), who desired tobacco. He was spotlessly clean, but his clothes were worn to the bitter end. I told him I could almost envy his untrammelled life. He replied that the romance of it evaporated in the winter months, that he was getting old, and that his teeth hurt him, and he was going to have them pulled out by some itinerant at the fair by Sannois. He quoted Pascal at me—"*A la fin, on mourra seul*" ("At the end, one will die alone")—and gratefully accepted the tobacco of the English and such small help as I could offer him.

In the boulevard, Champs Elysées, Paris. The agencies of Messrs. Humber, De Dion Bouton, and Hotchkiss are situated in the beflagged block of buildings.

From Paris to Rouen.

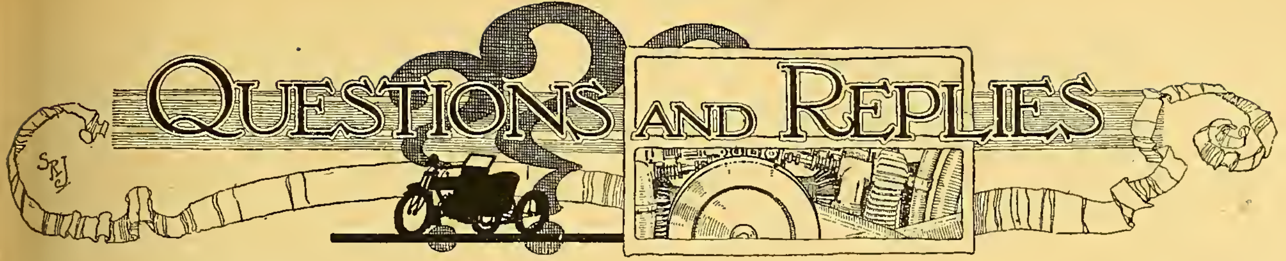
We came back from St. Germain by some tortuous route through Mesnil le Roi, and got most wonderfully lost, finishing up at a farmhouse, where we were royally entertained for a very small sum (in happy distinction from the sharks of Paris, who had bled us unmercifully on many occasions). The time passed all too quickly, and at last we had to think of the return journey. We decided to go by Rouen, one of the loveliest of old-world cities, and break our journey there. For the first few miles out of Paris the roadsides were placarded with advertisements of Hutchinson and Michelin tyres and the ubiquitous Rudge-Whitworth wire wheel. The road was all against us, long dragging rises and short, sharp descents. The villages through which we passed were gaily decorated, as to-morrow was the great Nation *fête*, the Quatorze Juillet, when everybody celebrat the taking of the Bastille, and nobody does any wo at all (always excepting the *café* proprietors, wl never seem to close, their zinc-topped tables alwa covered with brightly-coloured liqueurs of a heac nature). After sixty miles or so of rather ha driving, we slipped down one of those amazing ar rather terrifying hairpin hill roads to which the Fren are rather given, and which return to haunt you nightmares, and picked our way delicately along t quay *(pavé!)* to the C.T.C. hotel.

The National Fete.

After supper we went out on to the streets, all up by torchlight, and watched as fine a milita procession, accoi panied by mu as gay and infe tious, as you cou imagine. After th we bestrode roun abouts, a peculiar vertiginous varie (the French have use for anythi that does not mo quickly), and gene ally took in the f of the fair. T press of the crov (and perhaps t wandering eye of would-be demu damsel in a swir was responsible f my losing the coi pany of my frie for the remainder of the evening. I shall not t you how I consoled myself, but he has never be able to convince me that it was not he I saw later a paper carnival hat pressing a vivacious daughter France to more ice-cream cones.

The next morning the clamorous church bells awo us in the small hours. You begin your *fête* day ea in France, and get value out of it. We went to vi the Place, where the crazy gabled windows look down on the smouldering body of the Maid of Franc It is difficult in a moment not to realise a little of t tragedy. In those old streets the centuries close o one. And the cathedrals! To attempt to descri them would be a profanation. Ruskin's rather hac neyed definition, "frozen music," comes somewh near it—such shape might Beethoven's 27th Son take.

All things come to an end, so behold us at last huddled on the lee side of a light racing returning from the tourney, our little machines stow below. The immigration officer comes round as near the white cliffs, "Are you a Breetish subject Yes, we are home, and so till better times good-bye the "pleasant land of France."



QUESTIONS AND REPLIES

A selection of questions of general interest received from readers and our replies thereto. All questions should be addressed to the Editor, "The Motor Cycle," 20, Tudor Street, London, E.C.4, and whether intended for publication or not **must be accompanied by a stamped addressed envelope for reply.** Correspondents are urged to write clearly and on one side of the paper only, numbering each query separately, and keeping a copy for ease of reference. Letters containing legal questions should be marked "Legal" in the left-hand corner of envelope, and should be kept distinct from questions bearing on technical subjects.

The Driving Licence.

I drive a motor cycle carrier combination for a tradesman, and my driving licence will need renewing in a short time. Ought my employer or ought I to pay for the renewal? If he does, should the licence be made out in his name or in mine?—G.S.M.

This is a matter for private arrangement between yourself and your employer. You will have to make the application yourself, and enclose the 5s. fee with your application, but whether or not your employer reimburses the sum is, as we have said, a private matter lying between you and him. The licence, of course, must be taken out in your name.

Irregular Running.

I have a 3 h.p. twin 1914 Royal Enfield. The front cylinder was cracked, welded up and replaced, but the compression differs in the two cylinders. That in the front cylinder is good, but in the rear cylinder it is excellent. (1.) At almost all speeds, and even when running on the stand, the front cylinder fires through the silencer (*i.e.*, intermittently allows popping in the silencer). (2.) Although the carburetter and control appear good, I am unable to shut right off. (3.) Oil persistently exudes from the front cylinder head. Please tell me the cure for these troubles. I also have a 4 h.p. single-cylinder 1912 Bradbury, and have fitted a new Amac carburetter. It is a single-speed machine, and whether ridden solo or with sidecar will sometimes climb a stiff hill but stop as soon as it is over the top. Will you please tell me the reason?—W.C.

1-3.) The fact that oil is exuding from he front cylinder seems to indicate that his is not firing properly, and that oil is working past the piston rings; also, that he inlet dome is not a gas-tight fit. This could also account for the difference in he compression of the two cylinders. Are you sure the trouble is not due to warping as a result of unsatisfactory welding? The popping back may be due to too weak an inlet valve spring, or to he tappets requiring adjustment. (2.) Obviously your throttle control wire is oo short, and does not allow the throttle o close properly, and it is quite possible that the trouble might be cured by adustment. The trouble with your 4 h.p. ingle-cylinder, single-geared machine is most probably pre-ignition, due to the use of a plug the points of which project oo far into the cylinder and become ncandescent.

Failure to Start when Warm.

Can you please tell me why my $4\frac{1}{4}$ h.p. motor bicycle will not start when the engine is hot? I can get it to fire about two or three times, and then the machine will stop. The magneto is perfectly all right, and the engine was overhauled not very long ago. When cold the engine starts easily.—T.P.

We have come across similar symptoms before, and have found them very difficult to explain. It is just possible that the trouble is due to the carburetter being adjusted on the rich side, and the mixture is too rich for the engine to start when warm, or to condensation on the plug points.

Lightening a Piston.

I have had a new piston made for the rear cylinder of my 1911 Douglas. It weighs 1 oz. 7 drms. more than the old one. Will this have any effect on the running or wear of engine? If so, in what way? I have already drilled holes in order to reduce the weight.—A.S.

We should recommend you to drill further holes in the piston, so that the weight is the same as that of the original one, otherwise the balance of the engine will be upset. We should also recommend you to take expert advice, which should be available to you as you are in the R.F.C., as to the method of drilling the piston so as not to weaken it. We cannot well advise you, as we do not know exactly how you have already drilled the piston.

"THE MOTOR CYCLE" AND THE PAPER SUPPLY.

GREATER NEED FOR ECONOMY.

During 1918 the restriction on the import of paper and paper making material is very drastic, and it is important that no copies of this journal shall be wasted.

Every reader is requested, therefore, to assist the publishers in effecting the necessary economy by placing a definite order with a newsagent for a copy of "The Motor Cycle" to be reserved or delivered regularly each week.

High Petrol Consumption.

I am very dissatisfied with the petrol consumption of my 1916 6 h.p. and sidecar. I only get 45 m.p.g. I have a hot air intake, a copper jacket round the flood chamber and on to the cylinder, and the induction pipe lagged with asbestos string. I usually run without passenger. The timing has been repeatedly checked, and the valves trued. The jet is as fixed by the makers, and is the size recommended by the carburetter makers, and there is no popping back; still the consumption does not improve, although I am told by friends of mine that they get 65 and 70 m.p.g. on a similar machine.—H.A.W.

We think that the trouble is due to your using too large a jet. Though the existing jet is that recommended by the makers, you have not taken into consideration the fact that you are using a hot air intake, and, consequently, we feel confident that the engine will stand a smaller jet with this device, this being one of the advantages which should accrue through using it. Petrol consumption is also largely a matter of driving.

Electric Lighting.

I have a $2\frac{3}{4}$ h.p. Douglas engine used as a stationary unit driving a generator for a technical branch of the Royal Engineers. I am eager to fit up some sort of electric lighting set by which to light us up when working by night, as we often do, and I thought you might know of a dynamo-accumulator set which I could run from the engine, charging the accumulator by friction drive from the Douglas flywheel. The engine only runs for short periods of about five minutes at intervals, never for long periods together. Can you suggest a lighting set for these conditions? As a motor cyclist, I always use acetylene lighting; but has not some electric lighting set been evolved, such as I require?—F.R.

There are frequent advertisements in *The Motor Cycle* of such a set as you require, but whether the makers will be able to supply at the present time we cannot say. Personally, we should be very much inclined to doubt if any dynamo lighting set containing accumulators also could give satisfactory service, if it were being driven by an engine at short intervals only. However, the makers of whatever set you choose would give you full information on this point, and we should certainly place these circumstances before them and secure their opinion.

Poor Compression after fitting New Rings.

I should be much obliged if you could tell me what is wrong with my $3\frac{1}{2}$ h.p. single-cylinder. I recently had new piston rings fitted, and on assembling the engine I cannot get good compression. It will fire regularly enough, but will not pull. I have thoroughly examined the crank case and cylinder, also the valves, and cannot find any leakage. Is it possible that the air is blowing back past the rings?—L.U.U.

Possibly a new piston is required as well as new rings. Also, the new rings would require to be run in for a short time. Of course, it is possible that the ring slots may be in line owing to faulty assembling, and if this is the case you cannot get compression. After a little running they may perhaps re-arrange themselves.

Removing a Refractory Nut.

I should be much obliged if you would kindly tell me which is the best way to move the lock-nut on a 1914 Triumph adjustable pulley. I have tried to move it with the valve cap spanner and a mallet, but without success. I believe it is a right-hand thread on the nut and a left-hand thread on the pulley flange. Is this correct? I wish to reduce the gear, as at present it is $3\frac{5}{8}$ to 1 (top ratio), which is too high for winter riding.—W.H.B.

You are proceeding in the right way, and if you persevere you should be successful in removing the refractory nut. First try running some paraffin around the thread, then get a piece of rope or cord and wind it twice round the pulley, fastening one end and getting someone to hold the other so as to prevent it from turning, and after a few sharp blows with a heavy hammer the nut is bound to come undone. Evidently the thread must be rusted up and the nut is jammed. When the nut has been removed, the thread should be well greased. The gear is too high for any kind of riding, not only for winter work.

Scott Queries.

I have recently purchased a Scott motor cycle, but I cannot get it to start. Both plugs spark well when taken out of the cylinder, so I do not think the fault is in the magneto. The carburetter is a Binks, and I generally adjust the throttle one-third open when trying to start. (1.) With a vigorous kick I can push the starter right down without holding up the compression release. Is this in order? (2.) I took out the throttle and flooded the carburetter, and the petrol just came over the top of the jets. Should it spurt over the top of the jets? (3.) How can I test the magneto timing? (4.) How should I adjust the carburetter for starting?—C.P.A.

(1.) Yes. (2.) Yes. (3.) Set the contact breaker at two-thirds retarded, then revolve the engine until one piston is exactly on the top of its stroke. The make and break arms of the contact breaker segment for this cylinder should then be just separating. (4.) If the carburetter is a single-lever carburetter, the throttle should be about one-third open; if it is a double-lever carburetter, the throttle should be about one-third open and the air closed, but individual engines often require a slight modification of this arrangement. Thus, while some engines will only start if the throttle is rather more than half open, others will only start if it is open just a shade. All depends upon the main air supply, and we should imagine that this is the probable cause of your trouble. Try larger and smaller choke tubes.

A Broken Piston Ring.

(1.) I have a 1915 $2\frac{3}{4}$ h.p. Calthorpe-Jap, and would like to know why the inlet valve, spring, and tappet become so hot as practically to scorch up the frequent injections of oil which I have to give it. Is there any remedy for this? (2.) One of the two piston rings has become broken, and a piece about $\frac{3}{4}$in. long is missing. I cannot trace any sign of it in the cylinder, and take it that the broken piece has found a resting-place somewhere in the crank case. Would this explain a certain amount of loss of power which the engine has developed lately? (3.) I wish to take off the fixed Dixie magneto for cleaning, etc., but cannot move the nut holding the first timing cog. In what way can the remainder of the pinions and the engine be held rigid to enable me to remove the nut in question?—E.B.S.

(1.) It is quite impossible to prevent the inlet valve spring and tappet from becoming hot, because they are so close to the combustion chamber that the heat is naturally conducted to them. (2.) As to what has become of the broken piece, it is quite impossible to say, and you cannot tell if this is the source of the loss of power without taking the engine down and examining every part. (3.) It is best to prevent the engine from revolving by holding the back wheel pulley, or by some other convenient method, and putting a fairly long spanner on the nut, and then giving it a series of sharp taps with a hammer, when the nut should come undone without any trouble.

Flash-points.

Can you please give me flash-points of (1) petrol, paraffin, (3) hydrogen, and carbon monoxide? Also, are last two named gases suitable use in motor engines of high speed H.V.H.

As petrol and paraffin are both mixtu of other substances, it is difficult to ass to either of them a definite flash-poi That of petrol, however, may be tal as somewhere in the region of the fre ing point of water, while that of para may be about 150° Fahr. We do understand what you mean by the fla points of hydrogen and of carl monoxide, but the ignition temperatu of these two gases are about 580° C. hydrogen, and from 637° to 658° C. carbon monoxide. Hydrogen may be u as a fuel, but would be very expensi As regards carbon monoxide, this co possibly be used in theory, but we do think it would be a success in pract

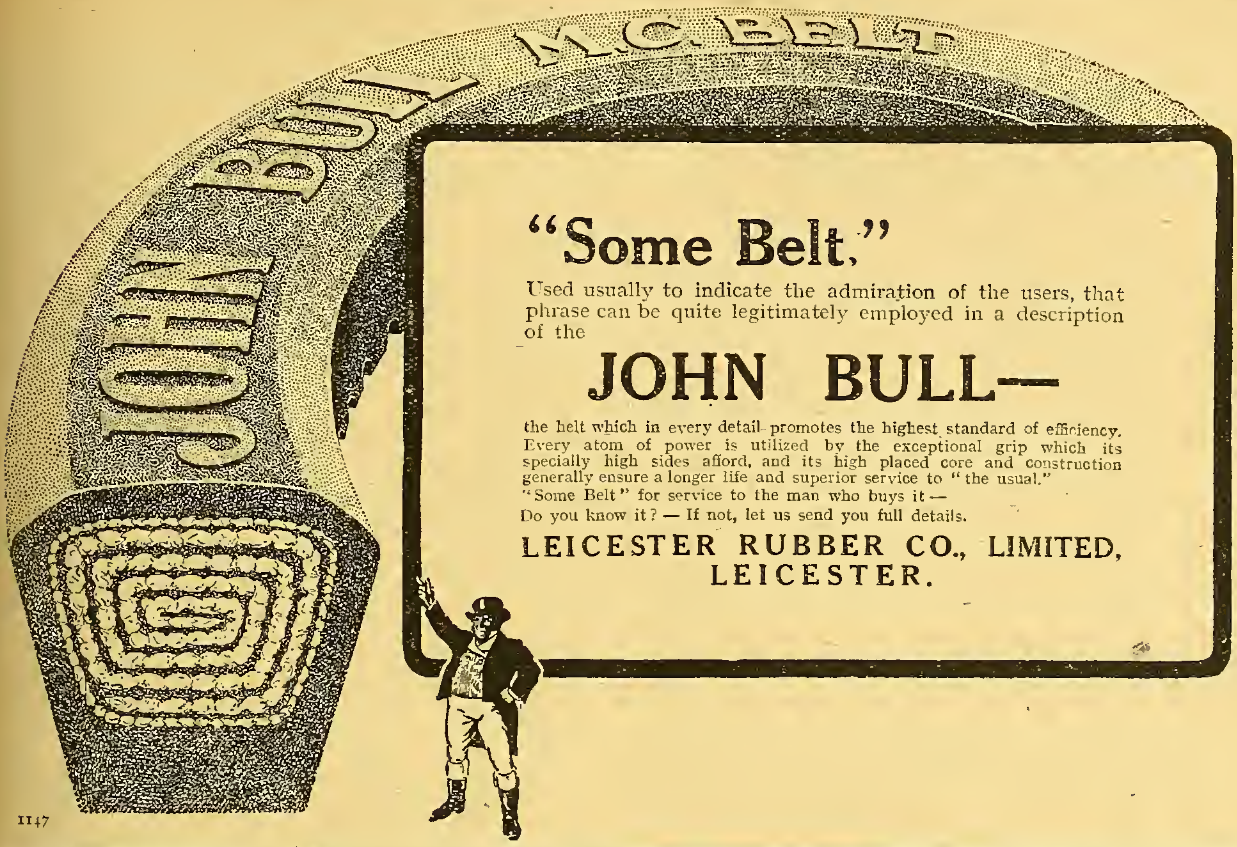
SIDE SLEDGING.

American motor cyclists enjoying a novel form of sport on the river Connecticut. The wheels and body of the sidecar have been removed and runners with spring seats attached in their place. (*Motor Cycling and Bicycling*, Chicago.)



"Some Belt."

Used usually to indicate the admiration of the users, that phrase can be quite legitimately employed in a description of the

JOHN BULL—

the belt which in every detail promotes the highest standard of efficiency. Every atom of power is utilized by the exceptional grip which its specially high sides afford, and its high placed core and construction generally ensure a longer life and superior service to "the usual."
"Some Belt" for service to the man who buys it—
Do you know it?—If not, let us send you full details.

DEFENCE OF THE REALM ACT

Under the provisions of the above Act, advertisers requiring workmen, and whose business consists wholly or mainly of engineering or the productions of munitions of war, or substances required for the production thereof, and whose works are situated within 30 miles of London, must include in every such advertisement the words, "No person resident more than 10 miles away, or already engaged on Government work, will be engaged."

Advertisers whose works are situated more than 30 miles from London can only have their announcements inserted with the approval of the Board of Trade, who will allocate to each advertisement a box number, and collect and distribute to the advertiser all replies received. The necessary forms of application can be obtained from any Labour Exchange or from the offices of this paper, and each advertisement must contain a clear reference to the effect that no person already engaged on Government work need apply.

MOTOR CYCLES FOR SALE.

Joint Research and the Motor Cycle.

I.—How it would Help the Motor Cyclist and the Home Industry.

WHILE the motor cycle of the present day represents a great improvement as compared with machines of ten years ago, no one would suggest that we have reached finality. As a matter of fact, it is not given to human beings to attain perfection. The most that we can hope is to approximate to it. Improvements in design may result from the individual efforts of manufacturers, largely influenced by the practical experiences of motor cyclists. Improvement effected in this way is in the first instance only local. One firm makes investigations which produce important results. These are embodied into its designs. It is only when the practical value of the improvement is proved on the road that other manufacturers, under pressure of public opinion, begin to fall into line. In so doing they are handicapped by not sharing with the originator the knowledge of exactly how the improvement came about, and on what theories of experiments it was based. It is clear that, if this same improvement had been the result of joint research by the whole industry, the consequences would be more generally and immediately beneficial. All British manufacturers would be equally in a position to apply and benefit by the results obtained. If the improvement can be made the subject of a patent, this patent would not be in the hands of one firm, but in the hands of the whole British industry, which would thus be given a noteworthy advantage over its foreign competitors. Inside the British industry no one firm would benefit at the expense of another, but all would benefit at the expense of the foreigner. The reputation of the British product would thus be further strengthened and sales rendered easier throughout the world's markets.

Meanwhile the motor cyclist would be getting better value for his money. The cost of research, being extended over a large number of manufacturers, would be trifling in any individual instance. Consequently, the improvement would be effected without any expenditure which would push up the cost of the machine. If the same improvement had been the result of individual research, the cost to the individual manufacturer would have been considerable. He would thus have been obliged to charge something extra for a machine embodying the improvement. If others wished to copy it, they would have to pay him a royalty. The result would tend to be an increased price all round. Thus it is clear that it is in the interests of motor cyclists that joint research should be conducted by the industry, and it is also to the benefit of the industry itself, the point to be realised being that at the present moment manufacturers cannot afford to dissipate their energies by any unnecessary internal competition, but must concentrate on the broad problem of keeping the British product ahead of the foreign one, and giving—as a whole—better value for money than can be offered by any other nation. It is only by doing this that we can get the lion's share of the world's markets.

The motor cyclist might perhaps imagine that it is of no consequence to him whether the British manufacturer succeeds in doing this or not, but he will be quite wrong in this opinion.

Another point is that the prosperity of the whole country, including the motor cyclist himself, depends on our ability to deal satisfactorily with the problem of employment. This cannot be done unless we widen our markets and increase our productions. Thus it is clear that it would be to the ultimate benefit of the British motor cycling industry if joint research were taken up on a generous scale.

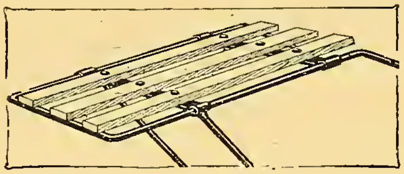
This matter of research is of vital importance, both to the motor cyclist and to the manufacturer, and we propose in the second part of this article to try and show how this valuable work can be conducted so as to make it a thoroughly sound business proposition to all concerned.

An index to the advertisements in this issue will be found on the page facing the back cover

IDEAS: Useful and Ingenious.

CARRYING SMALL PARCELS.

A DIFFICULTY is often experienced in attempting to carry small parcels on a motor cycle carrier when the space between the tubes is too large. To overcome this difficulty, attach three strips



A device enabling the carrier to be used for carrying small parcels.

of hard wood 1½in. to 2in. wide by ¼in. thick to the crossbar by means of bolts. Do not place the strips so close as to prevent two or three thicknesses of strap from passing between.—J.F.H.

SECURING INSULATING TAPE.

INSULATING tape is the chief friend of many motor cyclists, but in the majority of cases how shabby it looks, with ends hanging loose and edges all frayed, and its colour changed, by the adhesion of mud, into a dingy grey!

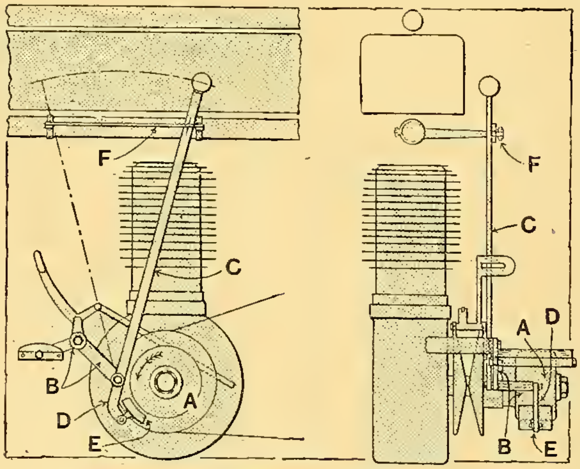
All these points can be prevented by painting it over, after the binding has been done, with a mixture of spirit black and ordinary opal or shellac varnish. This preparation, which is really a kind of French polish, dries fairly quickly with a glossy black finish, which entirely lacks the brittle nature of most ordinary enamels, and it seems to soak into and bind together all the tape wrapping. Unless the tape itself is of a superlatively sticky nature, it is advisable to fix down the last couple of inches or so with ordinary rubber solution.—J.B.S.

CONTROL LEVER FOR PHILIPSON PULLEY.

AS most readers are aware, the Philipson pulley is a patent governor pulley, which automatically varies the gear according to the stiffness of the gradient. It is also intended to be fitted with a handle-bar control (Bowden lever) for use in traffic, etc., which, by applying a slight retarding force to the motion of the brass boss (marked A in the sketch), drops the gear according to the force applied, by causing the inner and outer faces of the pulley to move further apart. On the braking force being removed, a spring contained in the boss causes the faces of the pulley to resume their original position.

On account of the war, I was unable to obtain the fitting to apply this braking force to suit my machine (a 1914 T.T. free engine Triumph), and accordingly had the arrangement shown fitted to my design. To the bracket which carries the foot brake pedal and footrest is fitted an auxiliary bracket B, bushed and fitted with a lubricator, to form a fulcrum for the hand lever C. The motion of the hand lever C is transmitted through a ⅝in. spindle to a shorter lever D about 2in. long, at the end of which is fixed a brake shoe E lined with leather. The hand lever is kept in its required position by a rack F, which is carried off the frame tube underneath the tank. A movement of about 2in. along the rack is found to give any required gear ratio when the engine is running, from 4 to 1 to the lowest available.

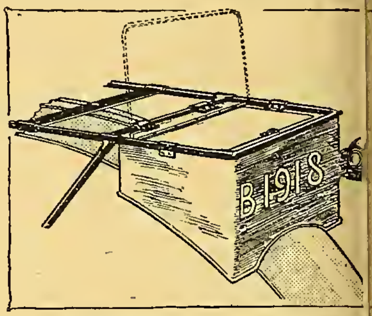
The fitting, which is a complete success, is found extremely useful for starting away from rest and for use in traffic. Before this arrangement was devised by the writer, it was necessary for the rider of the machine, when a low gear was required, to apply the necessary braking force with his left foot, which at the best of times is a crude and unmechanical method of using this most admirable pulley, for which the writer has nothing but praise, it being in every way satisfactory.—B K.



An ingenious idea for controlling a Philipson pulley.

IMPROVED TOOLBOX

THE toolbox shown, instead of l made of leather, consists of metal fitted securely to the fran the carrier, thereby making a neat strong fitment. The rear portion of

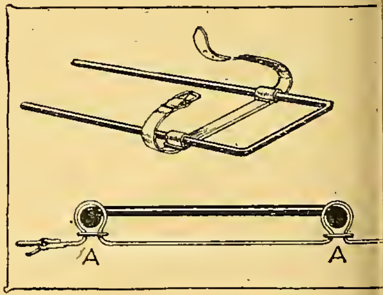


A combined toolbox and number plate.

toolbox takes the place of the u number plate, and a hinged lid is fi to the top portion. This design, whic registered, is extremely neat, and not get out of shape, as is the with the majority of leather tool ca W.H.B. (Dudley).

FIXING CARRIER STRAF

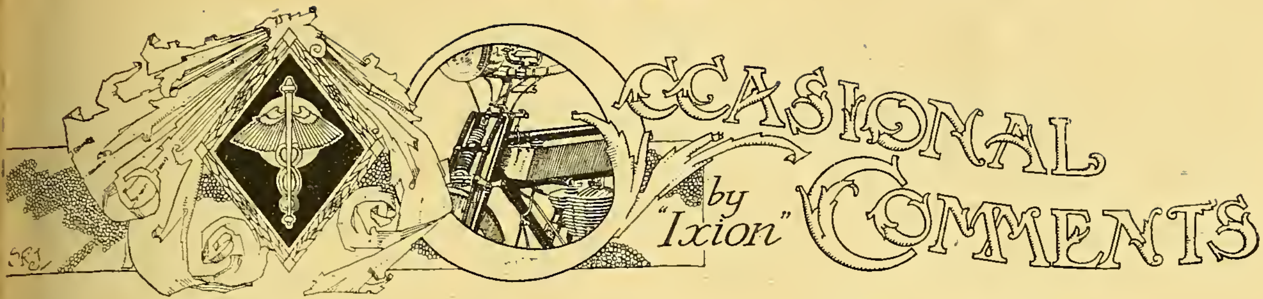
TO avoid the inconvenience of carry (and often losing) loose carrier stra the method shown in the sketch be found very effective. The points



How to secure carrier straps effectively.

are secured with wire. When not in the loose ends are lapped round the tr till just enough is left to buckle th together.—J.F.H. (Newcastle).

Readers of "The Motor Cycle" a invited to contribute to this page a ideas successfully adapted to their mot cycles. Contributions will be paid for our usual rates. Rough sketches w suffice.



Occasional Comments

by "Ixion"

British Magnetos.

MR. PENDRELL'S depreciation of the British magneto has already been pretty thoroughly dealt with. It is proved that in output and n quality of material we can equal the Bosch best, ınd, indeed, surpass it. There are other aspects of he question which are equally encouraging. Weight, or example. In road motoring, magneto weights are ıot a matter of supreme importance, but when a humping big aero engine requires four magnetos, it nakes a difference whether they weigh 20 lb. or 8 lb. ıpiece; the nett economy is equal to another machine gun, or a few extra drums of ammunition, and our nagnetos are the lightest in the world at the present noment. Again, originality counts for something. Magneto design in German hands had begun to stagnate; distributers and contact breakers, though every user could show you where they were unsatisfactory, ıad undergone no appreciable alteration for several ears. I suppose I mustn't describe some of the nstruments which I have seen lately, or I shall soon be dating my comments from Pentonville, or worse still from Dartmoor, where the Conchies are: so I nust be content with the remark that design has ceased to stagnate. Or again, the magnetos of nine-cylinder four-stroke engines run at two and a quarter imes engine speed; if the engine runs up to 2,000 .p.m. the magneto must run up to 4,500 r.p.m., and f the contact breaker is of the usual two cam type, he rocker arm must oscillate 9,000 times per minute. These are rather more strenuous demands than the average pre-war motor cycle could make; if British nagnetos satisfy them as thoroughly as they do, there s not much amiss.

Not a Monopoly Either.

IT must further be remembered that the British magneto industry is not of the hot-house order: it has not been built up under sheer compulsion behind a tariff wall. When war broke out, and caught us destitute of ignition gears, more than one Ally and neutral were able and ready to supply us with the requisite tackle. They possessed works, plant, experience, trained staffs, and supplies of such materials as they deemed suitable, and the manufacture of magnetos is one of the most delicate crafts in he world, analogous to making scientific instruments, plus the added difficulty of rather special materials. It was open to the Government to purchase its ignition abroad. British manufacturers, devoid of works, plant, staff, experience, and materials, had to build up their industry in the teeth of all these handicaps, and they secure the Government orders to-day not because their stuff is British or cheapest, but because it is the best.

A British Four-cylinder.

THE other day I encountered a British motor cycle fitted with a water-cooled four-cylinder engine. Wild horses will not drag the name of the maker from me, as it remains to be seen whether the type was evolved purely for military purposes, or whether it will blossom out into a production machine after the war. In the meantime, readers may be interested to hear a few details. The engine was a *monobloc*, mounted very far forward in the frame, and carried between duplex tubes, slung from a pair of long, straight tubes running from the steering head to the rear wheel spindle. The engine crankshaft was longitudinal with the frame, and the drive was transmitted through an epicyclic two-speed gear and bevels to a countershaft, from which an enclosed chain ran to the rear wheel sprocket. A single honeycomb radiator extended the full width of the machine just in front of the steering head. Engine lubrication was performed by the well-known trough system, and the sump carried sufficient oil for 1,000 miles. The petrol tank contained three gallons, and was by no means ungraceful in outline, being tapered towards the front, and fitting down snugly on top of the fore and aft diagonal frame members. A kick-starter was fitted. The engine was suspended at three points, and could easily be dropped clear for decarbonisation purposes, after the exhaust and inlet piping and the wiring had been cast loose. Gas was furnished by an automatic single lever carburetter. The weight of the outfit may be estimated at between five and six hundredweight, and the probable retail post-war cost at no less than £150.

What will it be up Against?

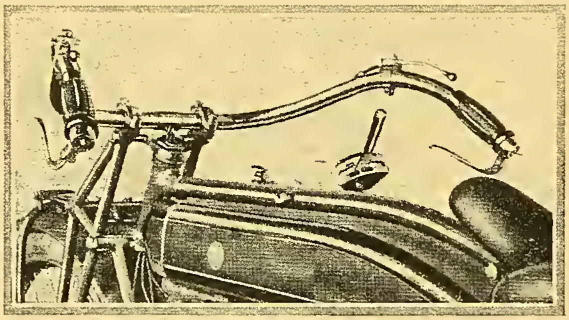
THIS machine may stand as an attempt to graft as many as possible of the advantages of a light car on to a three-wheeler. Such a mount should be practically the equivalent of a light car, except that it will take more handling round corners, suffers more from vibration, affords less protection to its driver, depreciates in value more rapidly, and carries less luggage. These are all serious defects in a comparison, but will be accepted by purchasers, as past trading history proves, *provided the outfit costs appreciably less* than four-wheelers which are free from these glaring faults. It is improbable that any light car will be produced within £50 of the sum for which such an ungainly three-wheeler can be manufactured. In other words, the costly and thumping sidecar outfit exists by favour of the cycle car. If anybody produces a decent cycle car, such as already exists on paper, the 10 h.p. water-cooled sidecar 'bus must scurry off the market double quick, otherwise it will probably survive.

RIDING POSITION.

A Plea for Adjustable Footrests and Handle-bars.

MOST riders of modest stature appreciate fully the convenience of adjustable footrests and handle-bars. Recently I lost a purchaser simply owing to the fact that my machine would not fit him. In every other respect he was delighted with it, but being short in the limb he was compelled to sit spreadeagle, as it were, arms and legs fully extended—a truly ludicrous spectacle that conveyed the impression that the machine was running away with him. For a small man to be compelled to ride in such a position must, indeed, be a sore trial in life, as no amount of saddle adjustment will permit the correct proportion of distances.

Quite apart from the question of stature, however, each rider has his individual tastes as regards riding position, and a considerable diversity of opinion exists as to what *is* the best position. The position that one man finds most restful may prove tiring to another, and again, some prefer one position for sidecar driving and another for solo use. The semi-T.T. position, which may be regarded as the best so far as controlling a solo mount is concerned, is generally unpleasant for sidecar use, so that the need for simple adjustment, giving a reasonably wide range of choice, is obvious.

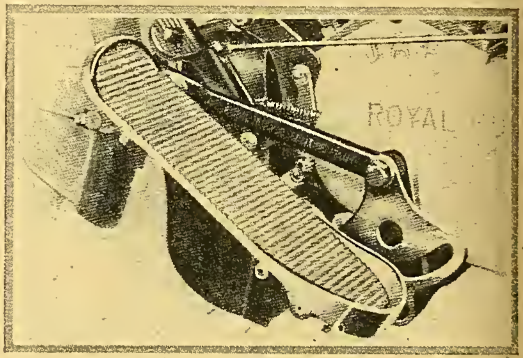


Adjustable handle-bars fitted to the A.B.C.

Riding Position.

Personally, I consider the position afforded by the Scott as ideal for sidecar use, but for solo use it falls short of perfect safety on a fast mount. Most Scott riders know this to their cost, having experienced that fatal front wheel skid when cornering at speed. The design of the Scott is such that one is tempted to take corners on the fast side, and with the touring bars it is merely a matter of time ere one comes to grief. Fit T.T. bars and the danger is removed, owing to the better control and the better judgment afforded by a proper feel of the machine.

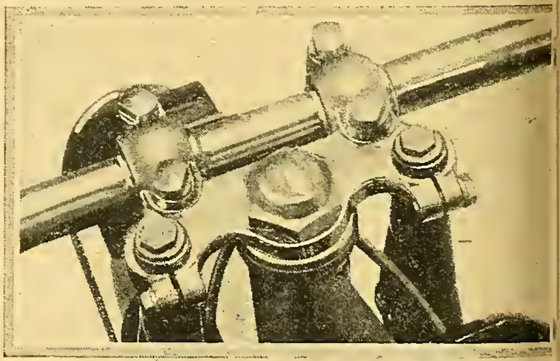
Personally, I consider that the best position for solo riding is one which permits the rider to sit upright with arms straight and fully extended when hold
the handle-bar grips in a natural position. W
riding naturally, one is then stooping very slightly f
ward, which counteracts the forward pull of



The Royal Ruby adjustable footboards.

machine, while the arms being straight less fatigue
felt than if the strain were taken through bent joir

As regards the matter of fatigue, even more depe
on the position of the footrests than on the position
the bars. Many riders make the mistake—and t
undoubtedly *is* a mistake—of riding with their fo
boards so far forward that they are unable to sust
any of their weight on their legs. The result is t
all their weight is on the saddle, and on a long ri
considerable fatigue is imposed upon the spi
Furthermore, with the footboards too far forward, ro
shocks are more keenly felt, broken saddle springs
experienced, and on rough going the rider is so mu
bounced about that his control of the machine is v
imperfect. A small man on a machine too large
him invariably experiences the discomfort of fo
boards too far forward.



The means of varying the handle-bar position on the Indian.

Riding Position.—

But, whatever be the worst or the best position, a wide margin remains for one's physical dimensions and personal choice. It is very seldom that a new machine passes into one's hands which exactly meets one's requirements as regards position—especially in the heavy sidecar class of mount. A slight adjustment of the bars and footrests, if such a thing were possible, would add enormously to one's comfort, and more than once I have effected an improvement by reversing the footboards or bending the handle-bars out of all resemblance to their former shape.

It would be a good plan to take a hint from the Americans as regards adjustable bars. The majority of their systems are entirely satisfactory in practice, and most riders would highly appreciate the possession of a bar which could be made semi-T.T. or touring at choice, and by means of a simple adjustment.

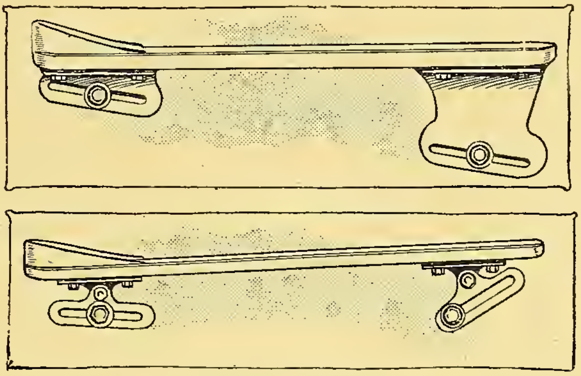
Adjusting the Footboards.

Adjustable footboards present greater difficulty, but only one movement is really necessary—that is, it should be possible to slide the boards backwards and forwards while they retain the same angle for one's feet. As a matter of fact, the boards should be almost parallel with the road; if anything, tilted very slightly upwards at the toe. In these days of low-built frames there is no question as to the man of short limb being able comfortably to reach the boards, and all that he requires is to be able to slide them backwards towards the saddle, so that he can sit without unnaturally extending his legs.

The design suggested herewith permits this movement, and, it being taken that only a man who is short in the limb will require the rests in the backwards position, the slots in the brackets mounting the rests could be set to determine the height also—the footboards rising when drawn back for a short rider, and falling when thrust forward. The second suggestion permits both movements, and also permits adjustment of the angle, which may occasionally be desirable to a small extent.

One feels convinced that if manufacturers would adopt such systems, free from gadgets and adding no unnecessary weight, they would be fully utilised.

CHINOOK.



Adjustable footboards suggested by "Chinook."

A CORRESPONDENCE.

A Queer Query anent the Reality or Fiction of the Personality of that Mysterious Walking (?) Encyclopædia "Ixion."

From A. R. Eader, Castroil Lodge, Revden, Hants.

DEAR IXION,—In June, 1914, I made a bet with a pal that "Ixion" does exist, and that he is not a masculine Mrs. 'Arris.

My friend alleged that whenever any member of *The Motor Cycle* staff had a few minutes to spare, or brain wave (don't blush), he dashed off something which appeared under the general heading of "Comments."

I, on the other hand, affirmed the existence of a genuine "Ixion," and further deduced from his articles that he was now of middle age, came from Tipperary (or at any rate was of Irish extraction), and that after a somewhat lurid youth was now respectably staid, and married. He has a family, including a son, who, when father is safely at the office, bags the latter's pet 5 h.p. single gear solo twin. "Ixion" objects to 3½ h.p. sidecar outfits, as Mrs. Ix is in the heavyweight class.

Well, the loser was to clean the winner's machine, and we were both allowing our mounts to get into a suitable condition when Potsdam Bill thought it was time to begin enlarging his dominions.

My friend, alas, will ride no more—unless Elysium has its roads—or I should have written before, and claimed the bet. Still, it has been intriguing me for some time, and an assurance that "Ixion" is a real person would greatly oblige.

I think, too, you are still a little fond of strong waters, after which you sometimes have deplorable lapses.

Yours truly,
A. R. EADER.

From "Ixion."

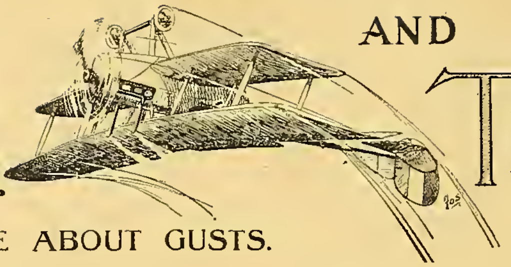
Dear Sir,—I have tried to duplicate your effort in literary analysis, but I fear with no very great success, partly ascribable to the fact that no heavy stakes spur my effort. At first I decided from evidences of intense curiosity in your letter that you were a female D.R. But anon, from your free treatment of the text under discussion I judged you to be a Broad Church parson, masquerading under a pseudonym. Finally, I decided to respect your evident desire for privacy, and to avoid prying into your hideous past and doubtless equally repulsive present.

As a matter of fact, you were a good deal nearer the mark than your friend—peace to his ashes: but here and there you allow yourself to make a false deduction. For example, my detestation of sidecars applies equally to the 7-9 h.p. variety.

In return for these sacred confidences I implore you to tell me where one may now procure those strong waters you speak of: I have been unable so much as to smell them these many moons past.

Yours faithfully,
"IXION."

FLYING FACTS AND THEORIE



MORE ABOUT GUSTS.

By W. G. ASTON, A.M.I.A.E.

IN my last article I described the effects of gusts having a resultant motion in the vertical plane of the fore and aft axis of the aeroplane. It will be seen that there are two other principal planes in which gusts can move, namely, the horizontal plane of the fore and aft axis, and the vertical plane of the transverse axis. Any imaginable gust must be either in one of these planes, or in some combination of them, and hence its total effect can readily be realised by considering to what each of its components gives rise. Dealing first with horizontal gusts, let us employ the compass points to denote the direction of the gust, the aeroplane being supposed to be flying in a straight line due north. Any gust which comes in this particular direction falls into the category that has already been considered, and so we need now only consider gusts which are at an angle to the line of flight. Looked at from above, an aeroplane is perfectly symmetrical about its fore and aft axis; hence only one half of the compass card need be discussed, as whatever happens on one side will have its counterpart on the other in the nett effect upon the machine, though the *direction* in which the subsequent disturbances take place will be reversed, of course.

Rolling.

Let us take a gust coming towards the aeroplane from the direction N.W. This produces two very important effects. First it alters the direction in which the air moves across the section of the main planes, and, second, it promotes a relatively sideways motion of the aeroplane, and in so doing generates upon the side surfaces a pressure, just as, in the ordinary way, the relative wind generates a pressure on the horizontal surfaces.

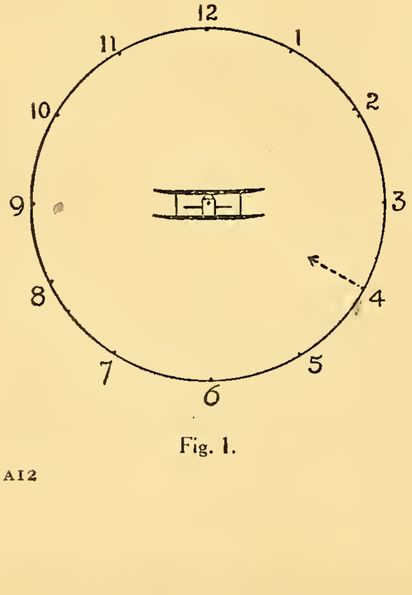


Fig. 1.

In regard to the first point, it will be seen that the main plane is no longer travelling broad edge first, but is moving diagonally. Since the centre of pressure always tends to be rather towards the leading edge than the trailing edge of a plane, this means that the C.P. moves from its previous central position, shown by a circle in fig. 1, and takes up a fresh position, as indicated by the +. As this C.P. is point of application of the upward lift force, anc no longer coincident with that of the downward fo due to the weight of the aeroplane, a couple is forn which tends to lift the western wing of the mach and to depress the eastern wing. In short, the mach "rolls" over to the position shown in fig. 2. T can be corrected immediately by the pilot, who, the flap, wing-warp gear, has means at h for promp making the ı chine roll the oppo direction, a so can, in moment, reinstate it upon an even keel.

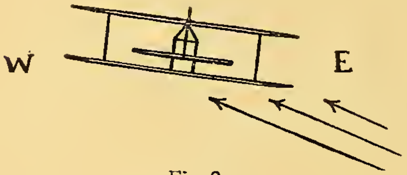

Fig. 2.

If the machine is not so controlled, it will if later stable (as most modern types are) correct itself side-slipping towards E. Such a side-slip will o more promote a diagonal movement of the air acr the main plane, but this time in the opposite directi That is to say, by side-slipping towards E the east wing tends to rise and the western to be depress hence if left to itself a stable machine will regain even keel on its own account, after being struck b gust, but to do it will roll first one way and then other. By exercising his control the pilot can av any discomfort arising from such movements.

The automatic recovery by rolling is enhanced a accelerated by the commonly employed dihedral ang

Weathercock Stability.

Next as to the effect of the fin, which is a fi directional surface mounted on the tail. When relatively sideways wind strikes the aeroplane position of the C.P. so caused will depend upon shape and size of the body, the amount of dihed angle, etc.. but, above all (since it is at the end of a long lever), upon the size of the fin. If this is big the lateral force will tend to be behind the C.G. of the machine, as shown in fig. 3, and so will tend to turn its nose towards

Flying Facts and Theories.—
the direction from which the gust is coming. This action is called "weathercock stability." On the other hand, if the fin is very small the reverse will take place, and the machine will tend to turn away from the gust. Whichever effect takes place the pilot can overcome it by means of the rudder, and the direction in which he will apply this organ will depend upon whether the machine is under-finned or over-finned. Most machines tend to follow the weathercock principle, but not all. It will easily be seen that there may be some particular surface of fin which would promote a turn neither in one direction nor the other, so that directionally the aeroplane need not be disturbed, though the sideways gust would still provoke a "roll." The correct dimensioning of the surfaces for this purpose is one of the most important factors in the design of an inherently stable aeroplane.

Pitching.

We must also not fail to take into consideration the fact that the gust, coming from the N.W., or diagonally, has a tendency to cause the machine to pitch. What we have already dealt with is principally its transverse component, and such pitching is caused by its longitudinal component. As pointed out in a previous article (see the issue of *The Motor Cycle* for February 28th), the effect of this head-on component will be such as first to tip the nose of the machine up and make it at once slow down and climb, afterwards, when the gust has passed, inducing it to tip its nose down and lose altitude.

The north-westerly gust, in the conditions outlined, thus exercises three distinct influences, all of which take effect at the same time. First, it tends to cause the machine to roll; secondly, it tends to cause the machine to pitch; and thirdly, according to the fin area, it tends to cause the machine to alter its direction. These three effects compose a form of disturbance which can, however, quickly be met by the controls at the command of the pilot.

Gusts in the Vertical Plane.

Turning now to gusts in the vertical plane, but this time transverse to the aeroplane, these can be denoted by a clock face in which the machine is supposed to have its fore and aft axis coincident with that of the hands of the clock, as indicated in fig. 4. Here, again, owing to the fact that the aeroplane is symmetrical in this plane, the effects of gusts from 12 o'clock to 6 o'clock (through 3 o'clock) will be exactly similar, in all but direction, to those which come from 12 o'clock to 6 o'clock (through 9 o'clock). As we have already dealt with such gusts as came from due 12 o'clock and from due 3 o'clock, it is now only necessary to consider diagonal ones coming, say, from 4 o'clock.

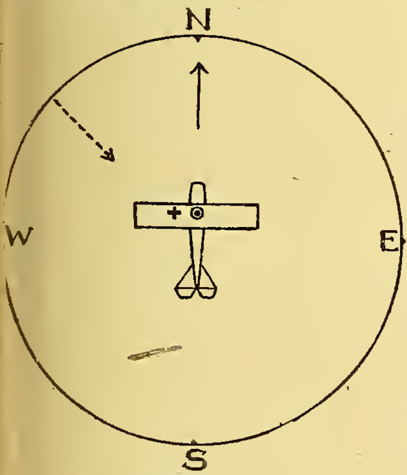

Fig. 4.

One from between 12 and 3 will yield similar results but in a different direction.

Composite Gusts.

When the gust is partially upwards and partially sideways, as shown in fig. 5, the fact that the plane now has a lateral angle of incidence and is travelling diagonally, instead of straight forward, promotes a movement of the centre of pressure towards that end which is entering the relative wind. Consequently a couple is formed which causes the machine to roll, so that its left wing is depressed and its right wing raised. This, again, is followed by a side-slip towards the left, which, especially with a dihedral angle, provides a restoring action.

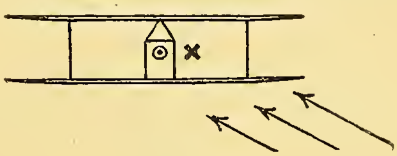

Fig. 5.

As the same time the gust has an effect upon the direction of the machine, causing it to turn its nose into the gust, if the tail fin be big, and *vice versâ*. It will thus be seen that, except for the pitching influence which the former exerts, a diagonal gust in the horizontal plane is exactly similar in result to one in the vertical plane.

Summary.

This can be summarised into the statement that, in general, gusts which are in the vertical plane of the longitudinal axis of the aeroplane will cause it only to pitch (leaving motions of translation out of the consideration for the time being), whereas any other gusts will cause it both to roll and to lose direction. Rolling being thus far more likely to occur than pitching, it follows that most of the work done by the pilot, in straight cross-country flying, is on the wing flaps, or ailerons.

When observing a machine either automatically correcting a roll or being restored to an even keel by the pilot, one can hardly fail to notice how quickly this evolution is carried out. It is, in fact, generally little more than a sort of "flick," whereas the correction of a pitch is a matter of more time. This is because the weights of the machine—pilot, passenger, engine, tanks, etc.—are so disposed in it that the moments of inertia about the fore and aft axis are very small—in other words, in the transverse section, all the principal weight is centrally situated. In consequence a roll can be very quickly checked, and especially so, since in this connection the amount of control available is very large, one flap lifting one side of the plane up whilst the other pushes its side of the plane down.

A machine of moderate size will roll through a complete circle in about five seconds, hence the correction of a roll of 10°, which amount will be very perceptible indeed, will only take about one-seventh of a second to perform.

MILITARY NOTES.

The A.S.C. in the Thick of it again. The Short Leave Petrol Licence.

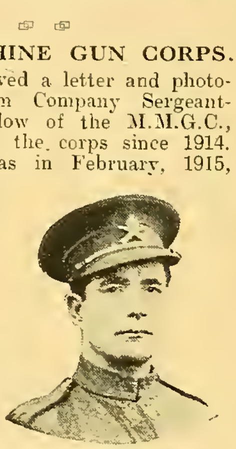
CROIX DE GUERRE AWARD.

WE are exceedingly pleased to learn that Temp.-Lt. D. S. Baddeley, A.S.C., formerly treasurer of the Motor Cycling Club and a well-known competition rider, has been awarded the Croix de Guerre by the King of the Belgians.

❧ ❧ ❧

MOTOR MACHINE GUN CORPS.

WE have received a letter and photographs from Company Sergeant-Major Harlow of the M.M.G.C., who has been in the corps since 1914. He went Overseas in February, 1915, was wounded in the second battle of Ypres, and he is now working at the depot. Sergeant-Major Harlow points out that the men in the group (reproduced on this page) have all returned from service Overseas, some from the L.A.M.B. and some from the M.G.C. Their average service Overseas is eighteen months.



Company Sgt.-Maj. F. J. Harlow, one of the few N.C.O.'s left who helped to form the Motor Machine Gun Service in Nov., 1914.

❧ ❧ ❧

A COVENTRY M.C. MEMBER PROMOTED.

CONGRATULATIONS to Sec.-Lt. Fred. J. Spencer, A.S.C., M.T., who got his commission recently after two years' service in the ranks in France. F.J.S. was a prominent member of the Coventry and Warwickshire M.C. in pre-war times and an indefatigable worker on the committee.

❧ ❧ ❧

THE M.T., A.S.C.

ALTHOUGH we have devoted a great deal of space to the evergreen subject of "Cushy Jobs" and "Danger of the M.T., A.S.C.," and have intimated that the topic has been fully treated, letters on the subject still pour in for our Military page. Among a batch recently to hand is one from Cpl. J. Rice, A.S.C., who says:

"May I defend the A.S.C. against that grossly unfair and wholly unfounded inference by 'Tank Driver' that this unit is never subjected to so great danger and hardship as is the combatant unit? Your correspondent asserts that an A.S.C. man has never driven a Tank into action, and I wish to reply that I am at present in daily contact with a man—not even transferred to the M.G.C. or Tank Corps—who is awaiting his discharge from the Army on account of the severe disabilities sustained while doing duty with a Tank in France. We have many other instances of a similar nature passing through daily, and even have men here who have been 'Tank instructors,' primarily recruited from the M T."

OFFICERS' DRESS.

OWING to the shortage of leather, officers are to be allowed to wear brown shoes when engaged in offices and when off duty. Khaki coloured socks must be worn on these occasions.

❧ ❧ ❧

DESPATCH RIDER FOR TWO AND A HALF YEARS.

WE had an interesting chat with Cpl. A. C. Webb last week, who is home on leave from Palestine, after two and a half years' service. On December 6th last we illustrated several of his photographs and gave a description of a D.R.'s life in Palestine. Among many things he said was that no one realises what the advance to Jerusalem was like, and the true story has yet to be written. Incidentally he mentioned that an important event in his life is taking place during his three weeks' leave, but the date of the marriage we did not learn. We wish him every happiness, and may good fortune be with him on his return to the Holy Land.

❧ ❧ ❧

PUTTING THE "TIN HAT" ON.

"BLIGHTY" writes: "I have been greatly amused at the letters on the topic 'Danger in the M.T.'

"'Tank Driver' seems to put the 'tin hat' on the whole thing by saying that he has never seen an M.T. man in any other capacity or place that our fighting troops would not call 'cushy.'

"I think that it would be a good thing if 'Tank Driver' would compare the casualty lists of the M.T. with that of the Tank Corps. He would be a bit surprised. I should advise him to keep his eyes open for a short time each day, and he might be able to see a few thousand M.T. men who have not got a job which our fighting troops would call 'cushy.'"

SPECIAL PETROL PERMIT

A NEW NON-LEAKING CARBURETTER.

A Design that was the Outcome of Experience with the Present Day Carburetter.

THE article by "Chinook," which appeared early in November, 1917, on "Which Type of Carburetter?" was a timely reminder that perfection has not yet been attained in this important adjunct to the motor cycle—indeed, more recent articles touching on other parts make one wonder if any single component part has, so far, reached that ultimate goal.

"Chinook's" indictment of present-day carburetters set me thinking about the carburetter troubles I have experienced on my 6 h.p. Clyno combination during 1917, and of the remedies devised, which ultimately led to the design of a new type, not perhaps inappropriately called a "non-leaking" carburetter.

But before enlarging on the defects of the old apparatus and the remedies devised to eliminate them, a word as to its design. It is a well-known, and in many respects a deservedly popular, type, with two-lever control, having a central gas regulating valve with a circular air valve surrounded by the latter. The fuel enters the spraying chamber through a number of holes placed across the path of the incoming air, and a good mixture is obtained for either slow or fast running. The slightest touch of the gas lever is reflected in the speed, and acceleration is as rapid as any ordinary rider could desire. Once fairly on the road with tight needle valve and a jet of suitable size for the kind of fuel being used, I have nothing but praise for this carburetter.

My first and constant trouble has been difficulty in starting. Notwithstanding perfect compression and certain ignition, I have never had entire confidence—born of successful experience—that I should get the engine started at the first attempt, and my repeated failures made me suspect one thing after another: leaky joints, badly fitting air valve, insufficient petrol or over-flooding. These were all in turn suspected, but no alteration produced any marked improvement.

Stopping Troubles.

The second trouble was of quite a different nature. Instead of a *starting* it was a *stopping* trouble I was up against. The importance of cooling the cylinders and pistons of air-cooled engines cannot be too strongly emphasised, so, with all sensible riders, I endeavour at every opportunity to cool my engine, and on every descent worthy of the name attempt to shut off the gas and give the engine full air. But, alas! the gas valve is not a real *shut-off* valve, and I have found it impossible to prevent the engine's firing without either cutting out the ignition or (undignified necessity) shutting the petrol cock on the tank, say, a hundred yards before reaching the descent and then having to open it again towards the bottom. Now I object to such a crude method of cooling an engine, but I more strongly object to the useless waste of precious fuel, which ought to be avoided by merely closing the gas valve.

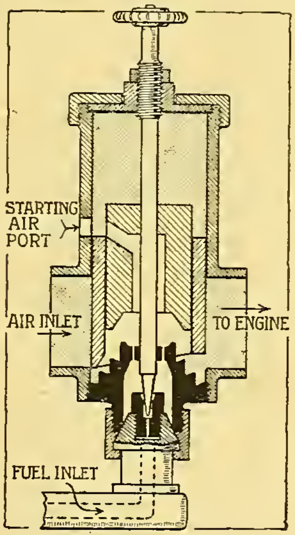
My third and last trouble I put down to the heavy war spirit now on the market, and to the attempt to economise by mixing paraffin with the spirit.

One other point, not so much a difficulty (as the cause was evident) but a serious source of waste, was occasioned by a leaky needle valve in the float chamber. Why should the overflow due to this be allowed to escape through the bottom of the carburetter and be lost?

Principles of the Carburetter.

Whilst it might interest the readers of this journal to follow the steps by which, one after the other, these defects were overcome, considerations of space forbid their recital. Suffice it to say that this was actually accomplished in the carburetter now fitted to my engine, which has the following features:

(1.) No holes at the bottom through which fuel can leak out. A rich starting mixture is obtained by admitting air from the *top*, through the centre of the gas valve, causing the air to impinge directly upon a shallow well of fuel, thus violently agitating it, and giving such a mixture that fires at the first attempt. Even if overflooded for starting up no fuel is lost, as it is retained in circular receptacles provided for that purpose, and is gradually used up as the engine runs.



The non-leaking carburetter designed by F. S. Inglis.

The Working.

(2.) A gas regulating valve which actually shuts off the fuel when in its closed position, the valve being centrally guided, and having a mitre face resting on a corresponding seat. The inlet from the float chamber is placed within the circle enclosed by the gas valve, and when coasting pure air alone can be admitted for cooling the cylinders, etc. Thus, a feature of the greatest importance is secured, which will go a long way to prevent overheating, with its loss of power, and also result in a considerable saving of fuel.

(3.) An adjustable jet, controlled by a needle valve operated from the top of the carburetter (thereby eliminating another source of leakage, as compared with that having adjustable jets at the bottom). A turn with finger and thumb gives a larger opening for heavier fuels, or for stiff climbing, etc., and a reverse turn brings it back to its original setting; thus a temporary increase in fuel is obtained whenever necessary without changing the jet.

(4.) Any leakage taking place through the needle valve in the float chamber is not lost, but must be used in driving the engine, as there are no openings in the bottom to allow it to escape.

A glance now at the sectional elevation of this carburetter will show that these advantages have been obtained in a simple, direct manner, and, as the moving parts are concentric one with the other, smooth and accurate working is assured. The Bowden wires have been omitted from the drawing, but these pass through the top, one on either side of the needle valve spindle, and are operated as usual from the handle-bar. Another minor feature worthy of notice is that the air port through the gas valve may be closed in every position of the air valve, so that whilst standing with a hot engine and the gas valve closed no petrol can be vaporised and pass out of the top air holes. The needle valve spindle, it will also be observed, acts as a central guide for the gas valve, and ensures accurate fitting on to its seat.

Results of Tests.

In order to test this new design, special permission was obtained from the authorities, and during December a few runs have been made. Before this I had the cylinders of the engine down and fitted new rings; consequently the compression was very poor, not supporting my weight on the starting lever as it did previously. In spite of this and the cold, frosty weather, the engine started regularly at first attempt. With the first experimental setting a speed of 34 m.p.h. was obtained with a total load of twenty-six stone, and the fuel consumption at the same time worked out at 54 m.p.g. The mixture proved, however, to be too rich, and difficulty was found in keeping the speed down to 10 m.p.h. on top gear. By lowering the petrol level, I have no doubt considerable improvements all round will be secured. No hill-climbing has yet been attempted, but when various adjustments of the carburetter have been tried and the best setting determined—which will at the same time run in the new rings and restore the compression—exhaustive tests, of course, will be made.

Two motorists have formed such a favourable opinion of the new design that they have invited the writer to design one on similar lines for car use, which they will fit to their cars. This is now on the way, with the addition of a pilot jet.

In the meantime, a patent has been applied for, and provisional acceptance has been secured.—F. S. INGLIS.

The Patent Office.

The Patent Office has long been a convenient butt for any abuse that might have been in need of a home, but we wonder how many readers are aware that this long-suffering institution dates from so distant a date as 1627?

A Note on Committees.

While we take no responsibility for the truth of the statement, we have heard it said by a "competent authority" that the complete list of committees now in existence under Government patronage occupies a thick closely-printed quarto volume.

The Industrial Reconstruction Council.

This organisation is working hard on its programme for attaining the millennium when the war is over. All interested may obtain full particulars as to how this desirable end may be simply attained on application to the Secretary, 8, Bouverie Street, E.C.4.

The Death of Mr. John Marston.

We recently announced the death of Mr. Roland Marston, of Sunbeam fame, and now very much regret to have to announce the death of his father also. Mr. John Marston died on Friday, the 8th inst., in his eighty-second year. He was practically the founder of the Sunbeam Motor Co., Ltd., and was also one of the first to recognise the possibilities of the motor car as a commercial proposition.

The Elusive Fuel.

The following figures, taken from the *Board of Trade Journal* for March 14th, show the number of petrol licences issued under each of the four separate issues of petrol licences made from Berkeley Street :

	LICENCES ISSUED.			
	First Issue.	Second Issue.	Third Issue.	Fourth Issue to 28th Feb., 1918.
Private cars .	94,111	84,610	70,452	54,719
Private cycles	95,098	48,580	34,462	27,303
Doctors' cars	14,636	11,966	10,250	9,050
Hackney vehicles	22,189	19,061	16,351	14,655
Commercial vehicles	35,677	32,290	38,880	31,706
Industrial processes	44,303	41,375	60,061	51,256
Total ..	306,014	237,882	230,456	188,689

German Propaganda.

Readers who have been interested in the correspondence we have recently closured on "Goods Made in Germany" are recommended to read two books, "Peaceful Penetration" (Constable, 3s. 6d.) and "The Bloodless War" (Hodder and Stoughton, 3s. 6d.) These deal with German trade methods, and the second shows how Germany obtained control of and practically ruined Italian trade enterprise.

Riding Position and Tall Riders.

Apropos of the article on page 272 of this issue, we had, recently, a chat with the works manager of a well-known firm on this matter. He acknowledged that their own machines were sinners in respect of discomfort to the tall rider, although we know of many worse. He assured us that their designers had expended considerable time on this point, with, only an unsatisfactory compromise as a result. He claimed that it should be possible to construct a system of adjustable footboards, handle-bars and saddle, so as to suit any rider to perfection, and he hoped before long that his firm would be able to make a distinct advance in the right direction. Without doubt this subject requires very serious attention by all designers, to prevent that weariness at the end of a long ride so well known to long-legged riders.

Special Features.

A NON-LEAKING CARBURETTER.
RIDING POSITION.
10,000 MILES WITH A DYNAMO LIGHTING SET.

Probable Influence of Aeroplane Practice on Engine Design.

Many of our readers have shown their interest in the influence that present aero engine practice may have on the future design of engines used in road vehicles. In *The Autocar* of March 16th is an interesting article on the probable results of aero practice in influencing future car engine design.

Bevel Gearing.

While bevel gearing is at present not very widely employed on motor cycles, there is every indication that its use will become more common in the future. Consequently motor cyclists should find much to interest them in an article published in this week's *Autocar*, discussing who was the first inventor of this form of gearing. Apparently an ancestor of Mr. Lionel Rapson, the inventor of the already well-known "Rapid" mechanical jack, patented this form of gearing so long ago as 1812, but if any reader of *The Motor Cycle* knows of any prior claim the Editor of *The Autocar* would be very glad to hear from him.

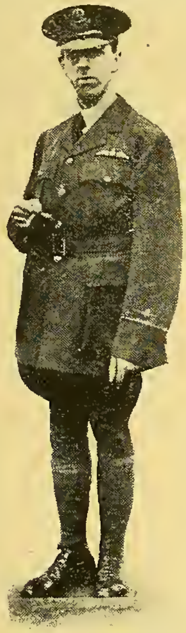
he Royal Air Force Uniform.

The new R.A.F. uniform should be istinctly attractive. The tunic is the rdinary service pattern; the rank is hown by means of ark brown rings n the cuffs, and re the same as hose in the Royal Navy—that is to ay, one ring for a ub or second-ieutenant, two for lieutenant, and so n. On each sleeve here is an albatross n gold, which was ormerly the badge f the Naval Flyng Service, and a rown. Officers are o wear a khaki ollar with the acket, and a black ie and gilt buttons. The black tie, of ourse, is another elic of a naval ustom. Slacks will lways be worn, exept in the case of ilots. The cap is omewhat like a aval cap in appearnce, has a stiff lack peak, a deep lack braid band ound the edge, a haki top, and over he peak the R.A.F. badge, consisting of ak leaves, an albatross, and the crown. After the war the uniform will be blue n colour, or rather the tint is more of a ark slate grey than blue. It is now orn as a mess jacket, in which case he ranks are shown by gold rings on he cuffs, as in the Navy.



The new uniform of an officer of the Royal Air Force.

mports and Exports.

The Board of Trade returns for Febuary show that only one motor cycle was imported, valued at £10. Accessories, tyres, etc., to the amount of £2,525 were received into the country.

Exports.

Compared with February, 1917, exports show a decline of £30,000. The value, including tyres, parts, etc., was £32,155.

	1916	1917	1918
Number of machines ..	1,133	882	508
Value of motor cycles, parts, etc.	£80,573	£66,142	£32,155

Another of Them.

The latest addition to the list of committees working under Government patronage is one to consider the "Resettlement of labour after the war." The duty of this particular committee, which has the honour of being appointed by the Ministry of Labour, is to advise the Government on matters connected with the resettlement of labour after the war consequent upon the demobilisation of the Forces, etc.

Its immediate interest to motorists is that Sir Herbert Austin, K.B.E., has been appointed to represent the Federation of British Industries on it.

A Raid Mystery.

A resident at Richmond complains that whenever a raid is taking place or a warning has been given, a large and brilliantly lighted car goes right through Richmond and along the Sheen and Upper Richmond roads, and is followed by a motor cycle and sidecar with exceedingly powerful lamps.

A Pointed Comment.

According to *John Bull*, some of the Petrol Controller's staff are conscientious objectors, employed at a salary of £300 a year. We should imagine that the comment of the average soldier who has been refused a licence by one of these gentry would be represented in print most expressively by —— * * *.

The Motor Users' Protection Association.

A meeting was held at the Cannon Street Hotel on Thursday last, the object of which was to found a new motoring organisation, which will be known as the Motor Users' Protection Association, the object of which may be said to advance generally the interests of motor vehicle users. The meeting was due to the initiative of Mr. H. E. Sanderson, 42, Howard Road, South Norwood, London, S.E.25.

The duties of the new association are apparently those which have already been the duties of existing motoring bodies, namely, to combat anti-motoring prejudice where it exists, to resist excessive taxation, to fight fuel rings or other trusts opposed to motoring interests, to prevent the imposition of unreasonable restrictions, and to see that the proceeds from motor taxation are spent on the improvement of the roads.

About forty people were present, and, provisionally, it was arranged to draft rules, to decide the amount of the annual subscription, and to determine generally the future position of the body.

Safety First.

On the occasion of an inquest held the other day on a widow who was knocked down by a D.R. in the Old Kent Road, Mr. Oddie, the Lambeth coroner, remarked: "The golden rule is to stand still."

Military Entertainments.
